Simultaneous Confidence Bands In Linear Regression Analysis

by

Pascal Soon Shien Ah-kine

Thesis for the degree of Doctor of Philosophy

December 11, 2009
Abstract

A simultaneous confidence band provides useful information on the plausible range of an unknown regression model. For a simple linear regression model, the most frequently quoted bands in the statistical literature include the two-segment band, the three-segment band and the hyperbolic band, and for a multiple linear regression model, the most common bands in the statistical literature include the hyperbolic band and the constant width band. The optimality criteria for confidence bands include the Average Width criterion considered by Gafarian (1964) and Naiman (1984) among others, and the Minimum Area Confidence Set (MACS) criterion of Liu and Hayter (2007). A concise review of the construction of two-sided simultaneous confidence bands in simple and multiple linear regressions and their comparison under the two mentioned optimality criteria is provided in the thesis. Two families of confidence bands, the \textit{inner-hyperbolic} bands and the \textit{outer-hyperbolic} bands, which include the hyperbolic and three-segment bands as special cases, are introduced for a simple linear regression. Under the MACS criterion, the best confidence band within each family is found by numerical search and compared with the hyperbolic band, the best three-segment band and with each other. The \textit{inner-hyperbolic} family of confidence bands, which include the hyperbolic and constant-width bands as special cases, is also constructed for a multiple linear regression model over an ellipsoidal covariate region and the best band within the family is found by numerical search. For a multiple linear regression model over a rectangular covariate region (\textit{i.e.} the predictor variables are constrained in intervals), no method of constructing exact simultaneous confidence bands has been published so far. A method to construct exact two-sided hyperbolic and constant width bands over a rectangular covariate region and compare between them is provided in this thesis when there are up to three predictor variables. A simulation method similar to the ones used by Liu \textit{et al.} (2005a) and Liu \textit{et al.} (2005b) is also provided for the calculation of the average width and the minimum volume of confidence set when there are more than three predictor variables. The methods used in this thesis are illustrated with numerical examples and the Matlab programs used are available upon request.

Declaration Of Authorship

I, Pascal Soon Shien Ah-kine, declare that the thesis entitled Simultaneous Confidence Bands In Linear Regression Analysis and the work presented in the thesis are both my own, and have been generated by me as the result of my own original research. I confirm that:

- this work was done wholly or mainly while in candidature for a research degree at this University;
- where any part of this thesis has previously been submitted for a degree or any other qualification at this University or any other institution, this has been clearly stated;
- where I have consulted the published work of others, this is always clearly attributed;
- where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work;
- I have acknowledged all main sources of help;
- where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself;
- none of this work has been published before submission. Parts of this work are intended to be submitted for publication as:
  - Liu, W. and Ah-Kine, P. Optimal Simultaneous Confidence Bands in Simple Linear Regression
  - Ah-Kine, P. and Liu, W. Optimal Simultaneous Confidence Bands in Multiple Linear Regression with Predictor Variables Constrained in an Ellipsoidal Region.
  - Liu, W. and Ah-Kine, P. Exact simultaneous confidence bands for a linear regression with predictor variables constrained in intervals.

Acknowledgements

Foremost, I would like to express my utmost gratitude to the School of Mathematics of the University of Southampton and the Overseas Research Students Awards Scheme (ORSAS) for funding my research. Not only was I given the honour to research in the statistical field but I was also given the opportunity to travel to various places to present my work.

This thesis would not have been possible without the caring supervision of Prof. Wei Liu. I am very grateful for his guidance, patience, motivation and immense knowledge he provided during the time of my research. Never short of brilliant ideas and insightful comments, Prof. Wei Liu has also given me the chance to meet and collaborate with other experts in the field of confidence bands. As a result, I have co-authored for the first time in the papers:

Subsequently, I have been actively collaborating with Prof. Wei Liu in writing several other papers, three of which are related to this thesis. Suffice it to say that I could not have imagined having a better supervisor and mentor for my PhD study.

Besides my supervisor, I would also like to thank the other member of my thesis committee, Dr. Dave Woods. His teaching, support and presence over the years have been valuable, mainly by being the statistical figure that I look up to. I would also like to thank my undergraduate personal tutor, Dr. Sujit Sahu, who guided me to the statistical field and encouraged me to take admission in the PhD study. My sincere thanks also go to all the staff, colleagues and friends of the School of Mathematics and the Southampton Statistical Sciences Research Institute (S3RI), in particular Antony Overstall who has been sharing an office with me for the whole duration of my research.

I dedicate my thesis to my supportive family, especially my parents Vincent and Josiane Ah-kine, for the spiritual, moral and financial support throughout my life. Finally, I would like to give praise to my other half, Amy Lim, who has provided me with encouragement, inspiration and affection throughout my PhD study.
Chapter 1

Introduction to linear regression analysis and simultaneous confidence bands

The term “regression” originates from the 14th century, where it had a biological meaning as “the act of going back”. It was first adapted to a more general statistical context by the well-known statisticians Udny Yule and Karl Pearson. However, its first statistical form was published by Legendre (1805) and by Gauss (1809) in the field of astronomy, where they applied the method of least squares to the problem of determining orbits of bodies about the Sun. Since then, regression analysis has been widely applied to the study of biology, behavioral and social sciences and more recently in finance, industry and many other practical aspects of real life.

The first widely studied form of regression analysis has been linear regression, due to the simplicity of the model and the statistical properties of the estimators. Linear regression is usually used for the purpose of hypothesis testing or for the purpose of prediction and forecasting. Many statistical methods and techniques have emerged from its study and one of them is the simultaneous confidence band. This chapter provides a general review of linear regression and presents some preliminary results necessary for the construction and comparison of simultaneous confidence bands throughout the thesis.

1.1 Linear regression models

Linear regression analysis is a statistical technique used to model data consisting of a dependent random variable and one or more independent variables, so as to evaluate the relationship between the dependent variable and the independent variables. Specifically, the dependent variable $y$ is expressed as a function of the independent variables $x_1, \ldots, x_k$, the corresponding parameters $b_0, b_1, \ldots, b_k$ and an error term $e$ as in

$$\begin{equation}
    y = b_0 + b_1 x_1 + b_2 x_2 + \ldots + b_k x_k + e.
\end{equation}$$
The error term $e$ is a random variable that represents the unexplained variation in the dependent variable $y$. If a sample of $n$ observations are available with the $i^{th}$ observation given by $(y_i, x_{i1}, x_{i2}, \ldots, x_{ik})$ for $i = 1, \ldots, n$, the $i^{th}$ observation is assumed to satisfy the relationship

$$y_i = b_0 + b_1 x_{i1} + b_2 x_{i2} + \ldots + b_k x_{ik} + e_i$$

where $b_0, b_1, \ldots, b_k$ are the same for all observations. The linear regression model can also be represented in the matrix form

$$Y = Xb + e$$

where $Y = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$, $X = \begin{pmatrix} 1 & x_{11} & \cdots & x_{1k} \\ 1 & x_{21} & \cdots & x_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_{n1} & \cdots & x_{nk} \end{pmatrix}$, $b = \begin{pmatrix} b_0 \\ b_1 \\ \vdots \\ b_k \end{pmatrix}$, and $e = \begin{pmatrix} e_1 \\ e_2 \\ \vdots \\ e_n \end{pmatrix}$.

The matrix $X$ is called the design matrix as its components can be suitably chosen via design. Moreover, the linear regression model is subject to the following assumptions:

- The errors follow a normal distribution with the mean zero and constant variance $\sigma^2 > 0$ and they are independent.
- The independent variables $x_1, \ldots, x_k$ are error-free and the design matrix $X$ has full column rank $k + 1$.

1.2 Parameter estimation

1.2.1 Least squares estimates

From the sample of $n$ observations, the linear regression model can be used to evaluate the relationship between the dependent variable $y$ and the independent variables $x_1, \ldots, x_k$ by estimating the parameters of the model. These include the $k + 1$ coefficients $b_0, b_1, \ldots, b_k$ and the variance $\sigma^2$ of the error term $e$. In order that all the $k + 2$ parameters can be estimated from the sample data, there should be at least $n \geq k + 2$ observations. A common method of estimating the parameters is the method of least squares.

Let $\hat{b} = (\hat{b}_0, \hat{b}_1, \ldots, \hat{b}_k)^T$ estimate $b = (b_0, b_1, \ldots, b_k)^T$ and let $\hat{\sigma}^2$ estimate $\sigma^2$. Then, $\hat{b}$ estimates $b$ by minimizing the sum of squares $\sum_{i=1}^{n} (y_i - b^T x_i)^2$ where $x_i = (1, x_{i1}, x_{i2}, \ldots, x_{ik})^T$.

Note that

$$\sum_{i=1}^{n} (y_i - b^T x_i)^2 = (Y - Xb)^T (Y - Xb) = \| Y - Xb \|^2$$

$$= Y^T Y - Y^T Xb - b^T X^T Y + b^T X^T Xb$$

$$= Y^T Y - 2b^T X^T Y + b^T X^T Xb$$
since $Y^T X b$ is a scalar and its transpose $b^T X^T Y$ is the same scalar. Now
\[
\frac{\partial}{\partial b} (Y^T Y - 2b^T X^T Y + b^T X^T X b) = -2X^T Y + 2X^T X b
\]
\[
= 0 \text{ at } b = \hat{b}.
\]
Hence, $X^T X \hat{b} = X^T Y$ and if $X$ has full column rank, then $X^T X$ is non-singular and so
\[
\hat{b} = (X^T X)^{-1} X^T Y.
\]
(1.3)

$$
1.2.2 \text{ Distributions of } \hat{b}, \hat{e} \text{ and } \hat{\sigma}^2
$$

Note that $\hat{b} = (X^T X)^{-1} X^T Y$, that is $\hat{b}$ is a linear transformation of $Y$, and $Y \sim N(Xb, \sigma^2)$. Therefore, $\hat{b}$ follows a normal distribution with mean
\[
E(\hat{b}) = E[(X^T X)^{-1} X^T Y]
\]
\[
= (X^T X)^{-1} X^T E(Y)
\]
\[
= (X^T X)^{-1} X^T X b
\]
\[
= b
\]
and variance
\[
Var(\hat{b}) = Cov[(X^T X)^{-1} X^T Y, (X^T X)^{-1} X^T Y]
\]
\[
= (X^T X)^{-1} X^T Cov(Y, Y) X (X^T X)^{-1}
\]
\[
= \sigma^2 (X^T X)^{-1}.
\]
Therefore,
\[
\hat{b} \sim N(b, \sigma^2 (X^T X)^{-1}).
\]
Since $\hat{e} = Y - X\hat{b} = (I_n - X(X^TX)^{-1}X^T)Y$, that is $\hat{e}$ is a linear transformation of $Y$, $\hat{e}$ also follows a normal distribution with mean

\[
E(\hat{e}) = E(Y - X\hat{b}) = E(Y - X(X^TX)^{-1}X^TY) = E[(I_n - X(X^TX)^{-1}X^T)Y] = (I_n - X(X^TX)^{-1}X^T)E(Y) = (I_n - X(X^TX)^{-1}X^T)Xb = Xb - X(X^TX)^{-1}X^TXb = 0
\]

and variance

\[
\text{Var}(\hat{e}) = \text{Cov}[(I_n - X(X^TX)^{-1}X^T)Y, (I_n - X(X^TX)^{-1}X^T)Y] = (I_n - X(X^TX)^{-1}X^T)\text{Cov}(Y, Y)(I_n - X(X^TX)^{-1}X^T) = \sigma^2(I_n - X(X^TX)^{-1}X^T)
\]

since $(I_n - X(X^TX)^{-1}X^T)$ is an idempotent matrix. Therefore,

\[
\hat{e} \sim N(0, \sigma^2(I_n - X(X^TX)^{-1}X^T)).
\]

For the distribution of $\hat{\sigma}^2$, note that

\[
\hat{\sigma}^2 = \frac{||Y - X\hat{b}||^2}{(n - k - 1)}
\]

where

\[
||Y - X\hat{b}||^2 = (Y - X\hat{b})^T(Y - X\hat{b}) = \hat{e}^T \hat{e} = [(I_n - X(X^TX)^{-1}X^T)Y]^T [(I_n - X(X^TX)^{-1}X^T)Y] = Y^T(I_n - X(X^TX)^{-1}X^T)Y \quad \text{(since} \quad (I_n - X(X^TX)^{-1}X^T) \quad \text{is idempotent)}
\]

\[
= (Xb + e)^T(I_n - X(X^TX)^{-1}X^T)(Xb + e) = e^T(I_n - X(X^TX)^{-1}X^T)e.
\]

Note that

\[
\text{trace}(I_n - X(X^TX)^{-1}X^T)
\]

\[
= \text{trace}(I_n) - \text{trace}(X(X^TX)^{-1}X^T)
\]

\[
= n - \text{trace}((X^TX)^{-1}X^TX) \quad \text{(since} \quad \text{trace}(AB) = \text{trace}(BA))
\]

\[
= n - (k + 1).
\]
Furthermore, $I_n - X(X^T X)^{-1}X^T$ is an idempotent matrix and so its rank is given by its trace. Therefore, there exists an $n \times n$ orthogonal matrix $G$ such that

$$I_n - X(X^T X)^{-1}X^T = G^T \begin{pmatrix} I_{n-(k+1)} & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} G.$$

Let $D = (D_1, D_2, \ldots, D_n)^T = Ge/\sigma$ so that $Ge = \sigma D$. Since $e/\sigma \sim N(0, I_n)$ and $G$ is orthogonal, $D \sim N(0, I_n)$. Hence,

$$\|Y - X\hat{b}\|^2 = e^T (I_n - X(X^T X)^{-1}X^T) e = e^T G^T \begin{pmatrix} I_{n-(k+1)} & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} G e = \sigma^2 D^T D = \sigma^2 (D_1^2 + D_2^2 + \ldots + D_{n-k-1}^2) \sim \sigma^2 \chi^2_{n-k-1}.$$

Therefore, the distribution of $\hat{\sigma}^2$ is given by

$$\hat{\sigma}^2 = \frac{\|Y - X\hat{b}\|^2}{n - k - 1} \sim \frac{\sigma^2 \chi^2_{n-k-1}}{n - k - 1}.$$

### 1.2.3 Independence of $\hat{b}$ and $\hat{e}$ and independence of $\hat{b}$ and $\hat{\sigma}^2$

Since $\hat{b}$ and $\hat{e}$ are normal random vectors and

$$\text{Cov}(\hat{b}, \hat{e}) = \text{Cov} \left[ (X^T X)^{-1}X^T Y, (I_n - X(X^T X)^{-1}X^T) Y \right] = \sigma^2 (X^T X)^{-1}X^T (I_n - X(X^T X)^{-1}X^T) \text{Cov}(\hat{e}, \hat{e}) = 0,$$

$\hat{b}$ and $\hat{e}$ are independent. Since $\hat{\sigma}^2 = \hat{e}^T \hat{e} / (n - k - 1)$, $\hat{b}$ and $\hat{\sigma}^2$ are also independent.

### 1.3 Uses of linear regression analysis

#### 1.3.1 Hypothesis testing

Given a linear regression model, one can test whether some regression coefficients $b$ satisfy certain constraints $Hb = h$, where $H$ is a given $r \times (k+1)$ matrix with full row rank $r \leq k + 1$ and $h$ is a given vector in $\mathbb{R}^r$. For this, one tests

$$H_0 : Hb = h$$

against $H_1 : Hb \neq h$. 

A size $\alpha$ test takes the form:

$$\text{Reject } H_0 \text{ if and only if } \frac{\left(\|Y - Xb_H\|^2 - \|Y - \hat{x}\|^2\right)}{\|Y - X\|^2/(n-k-1)} > f_{r,n-k-1}^\alpha$$

where $b_H$ is the least squares estimate of $b$, under the constraints $Hb = h$ and $f_{r,n-k-1}^\alpha$ is the upper $\alpha$ point of an $F$ distribution with degrees of freedom $r$ and $n-k-1$. This test can also be derived as the likelihood ratio test.

One common hypothesis test is to assess whether a predictor variable of interest $x_l$ add significantly to the prediction of the response $y$. In this case, the regression coefficient $b_l$ is set to zero, $H$ is set as a $1 \times (k+1)$ matrix with the $(1,l+1)$ entry equal to 1 and all the other entries equal to zero, and $h$ is set to 0.

1.3.2 Confidence and prediction intervals

Confidence and prediction intervals provide useful ways of assessing the quality of prediction at a single point. When considering the mean response $x^Tb$ of a model at a chosen $x = (1, x_1, x_2, \ldots, x_k)^T$, a confidence interval can be constructed to provide useful information on where the mean response lies. Since $x^T(\hat{b} - b) \sim N(0, \sigma^2 x^T(X^TX)^{-1}x)$ and since $\hat{b}$ is independent of $\sigma^2$,

$$\hat{x}^T(\hat{b} - b) \sim \sigma \sqrt{x^T(x^T)^{-1}x} \sim t_{n-k-1}$$

where $t_{n-k-1}$ is a $t$ distribution with $n-k-1$ degrees of freedom. Hence, a $1-\alpha$ confidence level for $x^Tb$ has the form:

$$P \left\{ x^Tb \in x^Tb \pm t_{n-k-1}^{\alpha/2} \hat{\sigma} \sqrt{x^T(X^TX)^{-1}x} \right\} = 1 - \alpha$$

where $t_{n-k-1}^{\alpha/2}$ is the upper $\alpha/2$ point of a $t$ distribution with $n-k-1$ degrees of freedom.

Moreover, when considering the value of future observation $y_f$ at a chosen $x = (1, x_1, x_2, \ldots, x_k)^T$, a prediction interval can be constructed to provide useful information on where $y_f$ lies. In that case, $y_f = x^Tb + e_f$ where $e_f$ is the random error associated with $y_f$. Note that

$$y_f - x^Tb = x^Tb + e_f - x^T\hat{b}$$
$$= e_f - x^T(\hat{b} - b)$$
$$\sim N(0, \sigma^2 + \sigma^2 x^T(X^TX)^{-1}x).$$

since $e_f \sim N(0, \sigma^2)$ and is independent of $\hat{b}$ and

$$\frac{y_f - x^T\hat{b}}{\hat{\sigma} \sqrt{1 + x^T(X^TX)^{-1}x}} \sim t_{n-k-1}.$$ 

Hence, a $1-\alpha$ prediction interval for $y_f$ can be derived from

$$P \left\{ y_f \in x^T\hat{b} \pm t_{n-k-1}^{\alpha/2} \hat{\sigma} \sqrt{1 + x^T(X^TX)^{-1}x} \right\} = 1 - \alpha.$$
1.4 Simultaneous confidence bands

When the entire range of values of the predictor variables is of interest, a simultaneous confidence band is used to make simultaneous confidence statements about the mean response \( x^T b \) for all the possible values of \( x \) within the range of interest. A simultaneous confidence band provides useful information on where the true but unknown regression lies. A linear regression model \( x^T b_0 \) is a plausible candidate for the unknown regression \( x^T b \) if and only if \( x^T b_0 \) is contained completely inside the confidence band.

Simultaneous confidence bands can take various forms depending on the preferences and requirements of the user. For instance, if one wishes to have a confidence band which has simultaneous coverage probability of \( 1 - \alpha \) and whose width is proportional to the standard error of the estimated regression function, then the Scheffé band can be used (see Scheffé, 1953). It has the form:

\[
x^T b \in x^T \hat{b} \pm \hat{\sigma} \sqrt{(k+1)f_{k+1,n-k-1}^{\alpha}} \sqrt{x^T (X^T X)^{-1} x} \quad \forall x \in \mathbb{R}^{k+1}
\]

where \( f_{k+1,n-k-1}^{\alpha} \) is the upper \( \alpha \) point of the \( F \) distribution with degrees of freedom \( k + 1 \) and \( n - k - 1 \).

Simultaneous confidence bands have now become a standard form of graphical illustration of results from statistical analysis. Although they are widely used nowadays, their construction is still a difficult problem for various regression models. Hence, the construction and comparison of exact two-sided confidence bands for various linear regression models are the main problems addressed in this thesis.

1.5 Outline of the thesis

The thesis consists of two main parts. The first part, which includes Chapter 2 and Chapter 3, covers the exact construction and optimality for two-sided simultaneous confidence bands in simple linear regression. The second part, which includes Chapter 4 and Chapter 5, covers the exact construction and optimality for two-sided simultaneous confidence bands in multiple linear regression. Specifically, in Chapter 2, the construction and comparison of some exact simultaneous confidence bands for simple linear regression are reviewed. Analytical and numerical methods are also carried out to show that D-optimal designs lead to the best confidence bands under a certain optimality criterion. In Chapter 3, two new families of simultaneous confidence bands are introduced and the best band within each family is identified numerically and compared to frequently quoted bands in the statistical literature. In Chapter 4, the construction and comparison of exact simultaneous two-sided confidence bands in multiple linear regression when the predictor variables are constrained in an ellipsoidal region are reviewed and a new family of simultaneous confidence bands is also introduced. A method to construct and compare of exact simultaneous two-sided confidence bands in multiple linear regression when the predictor variables are constrained in a rectangular region is proposed in Chapter 5. Finally, concluding remarks and possible future work are presented in Chapter 6.
Chapter 2

Exact simultaneous confidence bands in simple linear regression

2.1 The simple linear regression model

In simple linear regression, there is only one predictor variable in the regression model. The general model (1.1) is reduced to the response variable $y$ being expressed as a function of the independent variable $x$ and corresponding parameters $b_0$, $b_1$ and the error term $e$:

$$y = b_0 + b_1 x + e.$$ (2.1)

For a sample of $n$ observations where the $j^{th}$ observation is given by $(y_j, x_j)$ for $j = 1, \ldots, n$, the $j^{th}$ observation is assumed to satisfy the relationship:

$$y_j = b_0 + b_1 x_j + e_j.$$

The model in matrix form is the same as (1.2), that is $Y = Xb + e$. However, in simple linear regression, $X$ denotes the design matrix whose $i^{th}$ row is given by $(1, x_i)$ for $i = 1, \ldots, n$. So,

$$X = \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{pmatrix}$$

and

$$(X^T X)^{-1} = \frac{1}{\sum_{j=1}^n (x_j - \bar{x})^2} \begin{pmatrix} \frac{\sum_{j=1}^n x_j^2}{n} & -\bar{x} \\ -\bar{x} & 1 \end{pmatrix}$$

where $\bar{x} = \frac{1}{n} \sum_{j=1}^n x_j$. The least squares estimates of $b = (b_0, b_1)^T$ and $\sigma$ are denoted by $\hat{b} = (\hat{b}_0, \hat{b}_1)^T$ and $\hat{\sigma}$ respectively. In the simple linear regression case, $\hat{b} \sim N_2(b, \sigma^2(X^T X)^{-1})$ and $\frac{\hat{\sigma}}{\sigma} \sim \sqrt{\frac{\nu}{\nu}}$ where $\nu = n - k - 1 = n - 2$.

A $1 - \alpha$ level confidence band $(l(x), u(x))$ for the regression line $b_0 + b_1 x$ over an interval $x \in (a, A)$ has the form

$$\inf_{-\infty < l_0, b_1 < \infty, \sigma > 0} P\{l(x) < b_0 + b_1 x < u(x) \quad \forall x \in (a, A)\} = 1 - \alpha$$ (2.2)
where \( l(x) \) and \( u(x) \) are given functions representing the lower and upper parts respectively of the band, and \(-\infty \leq a < A \leq \infty \) and \( \alpha \in (0, 1) \) are given constants. The construction of simultaneous confidence bands for simple linear regression dates back to Working and Hotelling (1929) who obtained confidence bands for linear models when the variance is known. Since then, a considerable literature and work in the field has been made. For the case of unknown variance, Scheffé (1953) constructed hyperbolic confidence bands and Bowden and Graybill (1966) constructed straight line confidence bands. Wynn and Bloomfield (1971) and Uusipaikka (1983) provided exact confidence bands with width proportional to the standard error when the only predictor variable is restricted to an interval or union of intervals. Recent papers include Liu and Hayter (2007) who compare between confidence bands in simple linear regression and Liu, Lin and Piegorsch (2008) who provide methods for the construction of exact simultaneous confidence bands in simple linear regression.

In this chapter, we review the construction of the three most frequently quoted exact simultaneous confidence bands in the statistical literature, namely the two-segment band, the three-segment band and the hyperbolic band. More specifically, the two-sided confidence bands are considered, where the bands are symmetric about the estimated regression line \( \hat{b}_0 + \hat{b}_1 x \) and \( l(x) \) and \( u(x) \) are given by

\[
l(x) = \hat{b}_0 + \hat{b}_1 x - \hat{\sigma} H(x), \quad u(x) = \hat{b}_0 + \hat{b}_1 x + \hat{\sigma} H(x)
\]

where \( \hat{\sigma} H(x) > 0 \) is the half width of the band at \( x \) and \( H(x) \) determines the shape of the band.

## 2.2 Preliminaries

Before focusing on the construction of each of the three bands, some preliminary results used in the construction of the bands are presented. Let \( U \) be the unique square root matrix of \( (X^T X)^{-1} \) so that \( (X^T X)^{-1} = U^2 \). Using the results from Section 1.2.2 and applying them to simple linear regression, it is clear that

\[
\hat{b} \sim N_2(b, \sigma^2(X^T X)^{-1}), \quad \frac{\hat{\sigma}}{\sigma} \sim \sqrt{\frac{\chi^2_{n-2}}{n-2}}
\]

and \( \hat{b} \) and \( \hat{\sigma} \) are independent. Hence, \( N = U^{-1}(\hat{b} - b)/\sigma \sim N_2(0, I_2) \) and \( T = N/(\hat{\sigma}) = U^{-1}(\hat{b} - b)/\hat{\sigma} \) follows a bivariate \( t \) distribution (see Tong, 1990) whose probability density function is given by

\[
f_T(t_1, t_2) = \frac{1}{2\pi} \left[ 1 + \frac{1}{\nu} (t_1^2 + t_2^2)^{-\frac{\nu+2}{2}} \right], \quad (t_1, t_2) \in \mathbb{R}^2.
\]

Moreover, denote the polar coordinates of \( N = (N_1, N_2)^T \) and \( T = (t_1, t_2)^T \) by \( (R_N, \theta_N) \) and \( (R_T, \theta_T) \) respectively. For \( R_N \geq 0 \) and \( \theta_N \in [0, 2\pi) \),

\[
N_1 = R_N \cos \theta_N.
\]
\[ N_2 = R_N \sin \theta_N. \]

Then, \( R_N = \sqrt{N_1^2 + N_2^2} \sim \sqrt{\chi_2^2} \), \( \theta_N \) has a uniform distribution on the interval \([0, 2\pi)\), and \( R_N \) and \( \theta_N \) are independent random variables. Therefore,

\[ R_T = R_N / (\hat{\sigma} / \sigma) \sim \frac{\chi_2}{\chi_{n-2}^2/(n-2)} = \sqrt{2F_{2,n-2}} \]

where \( F_{k_1,k_2} \) denotes an \( F \) random variable with degrees of freedom \( k_1 \) and \( k_2 \). Furthermore, \( \theta_T \) has a uniform distribution on the interval \([0, 2\pi)\) and \( R_T \) and \( \theta_T \) are independent random variables. The cumulative distribution function of \( R_T \) is given by

\[
F_{R_T}(x) = P\{R_T < x\} = P\{\sqrt{2F_{2,n-2}} < x\} = P\{F_{2,n-2} < \frac{x^2}{2}\} = \int_0^{\frac{x^2}{2}} \left(1 + \frac{2u}{\nu}\right)^{-\frac{\nu+2}{2}} du
\]

since the pdf of the random variable \( F_{2,n-2} \) is given by \( f_{2,\nu}(u) = \left(1 + \frac{2u}{\nu}\right)^{-\frac{\nu+2}{2}} \), where \( \nu = n-2 \). Therefore,

\[
F_{R_T}(x) = 1 - \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu}{2}}. \tag{2.3}
\]

For a given vector \( \mathbf{v} \in \mathbb{R}^2 \) and constant \( r > 0 \), the set

\[
\{ \mathbf{T} : \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| < c \} \subset \mathbb{R}^2
\]

is made up of all the points that are on the same side as the origin of the straight line \( \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| = c \), where \( \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| = c \) is perpendicular to the vector \( \mathbf{v} \) and \( c \) distance away, in the direction of \( \mathbf{v} \), from the origin. Hence, the set \( \{ \mathbf{T} : \| \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| < c \} \subset \mathbb{R}^2 \), which can be expressed as \( \{ \mathbf{T} : \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| < c \} \cap \{ \mathbf{T} : (\mathbf{v})^T \mathbf{T} / \| (\mathbf{v}) \| = c \} \) is the stripe bounded by the parallel lines \( \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| = c \) and \( \mathbf{v}^T \mathbf{T} / \| \mathbf{v} \| = -c \). Finally, define a function \( v(c, d) \) as

\[
v(c, d) = \text{Var} \{ (c, d) \hat{\mathbf{b}} \} / \sigma^2
\]

\[
= \begin{pmatrix} c & d \end{pmatrix} (X^T X)^{-1} \begin{pmatrix} c \\ d \end{pmatrix}
\]

\[
= \begin{Bmatrix} U \left( \begin{array}{c} c \\ d \end{array} \right) \end{Bmatrix}^T \begin{Bmatrix} U \left( \begin{array}{c} c \\ d \end{array} \right) \end{Bmatrix}
\]

\[
= \left\| U \left( \begin{array}{c} c \\ d \end{array} \right) \right\|^2
\]

which will be used in deriving the form and confidence level of the bands.
2.3 Some exact simultaneous confidence bands

2.3.1 Two-sided two-segment bands

A two-sided two-segment band has

$$H_{2,2}(x) = c_{2,2,1} \sqrt{v(1, x)} + c_{2,2,2} |x - \bar{x}| \sqrt{v(0, 1)}, \quad x \in (-\infty, \infty)$$  \hspace{1cm} (2.4)

where the critical constants $c_{2,2,1}$ and $c_{2,2,2}$ are chosen so that the confidence level of the band is equal to $1 - \alpha$. The form of the two-sided two-segment band is illustrated in Figure 2.1. The band satisfies the following probability:

$$P\{b_0 + b_1 x \in [\hat{b}_0 + \hat{b}_1 x \pm \hat{\sigma} H_{2,2}(x)] \forall x \in (-\infty, \infty)\} = 1 - \alpha.$$  

The probability can also be expressed as

$$P\left\{ \sup_{x \in (-\infty, \infty)} \left| \frac{(1,x)(\hat{b} - b)/\hat{\sigma}}{H_{2,2}(x)} \right| < 1 \right\} = 1 - \alpha.$$  

Note that

$$\frac{\partial}{\partial x} \left\{ \frac{(1,x)(\hat{b} - b)/\hat{\sigma}}{H_{2,2}(x)} \right\}$$

has a fixed sign, either positive or negative, over $x < \bar{x}$ and $x > \bar{x}$. The supreme is therefore attained at either $x = \bar{x}$ or limits $x \to -\infty$ or $x \to \infty$. So, the confidence level can be further expressed as

$$P\left\{ \sup_{x = -\infty \text{ or } \bar{x} \text{ or } \infty} \left| \frac{(1,x)(\hat{b} - b)/\hat{\sigma}}{H_{2,2}(x)} \right| < 1 \right\} = P\{T \in R_2\}$$
where \( R_2 = R_2(-\infty) \cap R_2(\bar{x}) \cap R_2(\infty) \) with

\[
R_2(\bar{x}) = \left\{ T : \frac{|(1, \bar{x})(\hat{b} - b)/\hat{\sigma}|}{H_{2,2}(\bar{x})} < 1 \right\}
\]

\[
= \left\{ T : \left\{ U \begin{pmatrix} 1 \\ \bar{x} \end{pmatrix} \right\}^T T / c_{2,2,1} \sqrt{v(1, \bar{x})} < 1 \right\}
\]

\[
= \left\{ T : \left\{ U \begin{pmatrix} 1 \\ \bar{x} \end{pmatrix} \right\}^T / \left\| U \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\| < c_{2,2,1} \right\}
\]

and

\[
R_2(-\infty) = R_2(\infty) = \left\{ T : \lim_{x \to \infty} \frac{|(1, x)(\hat{b} - b)/\hat{\sigma}|}{H_{2,2}(x)} < 1 \right\}
\]

\[
= \left\{ T : \left\{ U \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}^T T / \left\| U \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\| < c_{2,2,2} \right\}.
\]

Using the results from Section 2.2, \( R_2 \) is hence found to be the region given by a parallelogram whose sides are given by the lines which are \( c_{2,2,2} \) and \( c_{2,2,1} \) distance away from the origin and perpendicular to the vectors \( U(0, 1)^T \) and \( U(1, \bar{x})^T \) respectively. \( R_2 \) is illustrated in Figure 2.2. The angle formed by the vectors \( U(0, 1)^T \) and \( U(1, \bar{x})^T \) is \( \pi/2 \) since the cosine of that angle is given by

\[
\left\{ U \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\}^T \left\{ U \begin{pmatrix} 1 \\ \bar{x} \end{pmatrix} \right\} = \left( 0 \ 1 \right)(X^TX)^{-1} \begin{pmatrix} 1 \\ \bar{x} \end{pmatrix} = 0.
\]

Therefore, \( R_2 \) is given by a rectangular region. The confidence level of the two-sided two-segment band is given by the probability of \( T \) in \( R_2 \). Let \( R_2^* \) be the region that
is resulted from rotating $R_2$ around the origin to the position so that $U(1, \bar{x})^T$ is in the direction of the $t_1$-axis and $U(0, 1)^T$ is in the direction of the $t_2$-axis, as shown in Figure 2.3. Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $R^*_2$ is equal to the probability of $T$ in $R_2$. Furthermore, the probability of $T$ in $R^*_2$ is equal to twice the probability of $T$ in the top-right half of $R^*_2$, which can be expressed as

$$\{T : \theta_T \in [-(\pi - \eta_2), \xi_2], R_T \cos \theta_T \leq c_{2,2,1}\} \cup \{T : \theta_T \in [\xi_2, \eta_2], R_T \cos (\theta_T - \pi/2) \leq c_{2,2,2}\}$$

where the angles $\xi_2$ and $\eta_2$ are depicted in Figure 2.3 and given by

$$\xi_2 = \sin^{-1}\left(\frac{c_{2,2,2}}{\sqrt{c_{2,2,2}^2 + c_{2,2,1}^2}}\right)$$

and

$$\eta_2 = \cos^{-1}\left(\frac{-c_{2,2,1}}{\sqrt{c_{2,2,2}^2 + c_{2,2,1}^2}}\right).$$

Hence, the probability of $T$ in $R_2$ is given by

$$P(T \in R_2) = 2P\{T : \theta_T \in [-(\pi - \eta_2), \xi_2], R_T \cos \theta_T \leq c_{2,2,1}\} + 2P\{T : \theta_T \in [\xi_2, \eta_2], R_T \cos (\theta_T - \pi/2) \leq c_{2,2,2}\}$$

$$= 2 \int_{-(\pi - \eta_2)}^{\xi_2} \frac{1}{2\pi} P\{R_T \cos \theta \leq c_{2,2,1}\} d\theta + 2 \int_{\xi_2}^{\eta_2} \frac{1}{2\pi} P\{R_T \cos (\theta - \pi/2) \leq c_{2,2,2}\} d\theta$$

$$= \frac{1}{\pi} \int_{-(\pi - \eta_2)}^{\xi_2} F_{R_T}\left(\frac{c_{2,2,1}}{\cos \theta}\right) d\theta + \frac{1}{\pi} \int_{\xi_2}^{\eta_2 - \frac{\pi}{2}} F_{R_T}\left(\frac{c_{2,2,2}}{\cos \theta}\right) d\theta.$$  

(2.5)

(2.6)
where the function $F_{RT}(x)$ is defined by expression (2.3), equality (2.5) follows directly from the uniform distribution of $\theta_T$ and equality (2.6) follows directly from the cumulative distribution function of $R_T$.

2.3.2 Two-sided three-segment bands

A two-sided three-segment band has

$$H_{3,2}(x) = \frac{1}{A-a}\{(x-a)c_{3,2,1}\sqrt{v(1,A)} + (A-x)c_{3,2,2}\sqrt{v(1,a)}\}, \quad x \in (a,A)$$

(2.7)

where the critical constants $c_{3,2,1}$ and $c_{3,2,2}$ are chosen so that the confidence level of the band is equal to $1 - \alpha$. The form of the two-sided three-segment band is illustrated in Figure 2.4. For $x$ outside of $(a,A)$, the band is formed of straight lines corresponding to the diagonal extensions of the band within $(a,A)$ and thus, the upper and lower parts of the band each consists of three line segments. The band satisfies

$$P\{b_0 + b_1x \in \hat{b}_0 + \hat{b}_1x \pm \hat{\sigma}H_{3,2}(x) \forall x \in (a,A)\} = 1 - \alpha.$$

The probability on the left side of the equality can be expressed as

$$P\left\{\sup_{x \in (a,A)} \frac{|(1,x)(\hat{b} - \hat{b})/\hat{\sigma}|}{H_{3,2}(x)} < 1\right\}.$$

As in section 2.3.1,

$$\frac{\partial}{\partial x} \left\{\frac{|(1,x)(\hat{b} - \hat{b})/\hat{\sigma}|}{H_{3,2}(x)}\right\}$$

has a fixed sign, either positive or negative, over $x \in (a,A)$. The supreme is therefore attained at either $x = a$ or $x = A$. So, the confidence level can be further expressed as

$$P\left\{\sup_{x=a \text{ or } A} \frac{|(1,x)(\hat{b} - \hat{b})/\hat{\sigma}|}{H_{3,2}(x)} < 1\right\} = P\{T \in R_3\}.$$
where $R_3 = R_3(a) \cap R_3(A)$ with

$$R_3(a) = \left\{ T : \frac{\left| (1,a)(\hat{b} - b)/\hat{\sigma} \right|}{H_{3,2}(a)} < 1 \right\}$$

$$= \left\{ T : \left\{ U \left( \begin{array}{c} 1 \\ a \end{array} \right) \right\}^T T / c_{3,2,2} \sqrt{v(1,a)} < 1 \right\}$$

$$= \left\{ T : \left\{ U \left( \begin{array}{c} 1 \\ a \end{array} \right) \right\}^T T / \| U \left( \begin{array}{c} 1 \\ a \end{array} \right) \| < c_{3,2,2} \right\}.$$  

Similarly,

$$R_3(A) = \left\{ T : \left\{ U \left( \begin{array}{c} 1 \\ A \end{array} \right) \right\}^T T / c_{3,2,1} \sqrt{v(1,A)} < 1 \right\}$$

$$= \left\{ T : \left\{ U \left( \begin{array}{c} 1 \\ A \end{array} \right) \right\}^T T / \| U \left( \begin{array}{c} 1 \\ A \end{array} \right) \| < c_{3,2,1} \right\}.$$

The region $R_3$ is given by a parallelogram whose sides are given by the lines which are $c_{3,2,1}$ and $c_{3,2,2}$ distance away from the origin and perpendicular to the vectors $U(1,a)^T$ and $U(1,A)^T$ respectively. The region $R_3$ is illustrated in Figure 2.5. The angle $\phi$ is formed by the vectors $U(1,a)^T$ and $U(1,A)^T$ and can be calculated from

$$\cos \phi = \frac{\left\{ U \left( \begin{array}{c} 1 \\ a \end{array} \right) \right\}^T \left\{ U \left( \begin{array}{c} 1 \\ A \end{array} \right) \right\}}{\| U \left( \begin{array}{c} 1 \\ a \end{array} \right) \| \| U \left( \begin{array}{c} 1 \\ A \end{array} \right) \|}$$

$$= \frac{\left( 1, a \right) (X^T X)^{-1} \left( \begin{array}{c} 1 \\ A \end{array} \right)}{\sqrt{v(1,a)v(1,A)}}.$$  

(2.8)
Note that $\cos \phi$ is also the correlation coefficient between $b_0 + b_1 a$ and $b_0 + b_1 A$. The confidence level of the two-sided three-segment band is given by the probability of $T$ in $R_3$.

Let $R^*_3$ be the region that is resulted from rotating $R_3$ around the origin to the position so that $U(1, A)^T$ is in the direction of the $t_1$-axis, as shown in Figure 2.6. Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $R_3$ is equal to the probability of $T$ in $R^*_3$, which is further equal to twice the probability of $T$ in the top-right half of $R^*_3$, which can be expressed as

$$\{T : \theta_T \in [-(\pi - \eta_3), \xi_3], \ R_T \cos \theta_T \leq c_{3,2,2}\} \cup \{T : \theta_T \in [\xi_3, \eta_3], \ R_T \cos (\theta_T - \phi) \leq c_{3,2,2}\}$$

where angles $\xi_3$ and $\eta_3$ can be derived using trigonometric calculations to be:

$$\xi_3 = \sin^{-1} \left( \frac{c_{3,2,2} - c_{3,2,1} \cos \phi}{\sqrt{c_{3,2,2}^2 + c_{3,2,1}^2 - 2c_{3,2,2}c_{3,2,1} \cos \phi}} \right)$$

and

$$\eta_3 = \cos^{-1} \left( \frac{-c_{3,2,1} \sin \phi}{\sqrt{c_{3,2,2}^2 + c_{3,2,1}^2 + 2c_{3,2,2}c_{3,2,1} \cos \phi}} \right).$$
Hence, the probability of $T$ in $R_3$ is equal to

$$P(T \in R_3) = 2P(T : \theta_T \in [-(\pi - \eta_3), \xi_3], R_T \cos \theta_T \leq c_{3,2,1}) + 2P(T : \theta_T \in [\xi_3, \eta_3], R_T \cos (\theta_T - \phi) \leq c_{3,2,2})$$

where the function $F_{RT}(x)$ is defined by expression (2.3). Thus, the confidence level of a two-sided three-segment band is given by expression (2.9).

2.3.3 Two-sided hyperbolic bands

A two-sided hyperbolic band has

$$H_{h,2}(x) = c_{h,2} \sqrt{v(1,x)}, \quad x \in (a,A)$$

where the critical constant $c_{h,2}$ is chosen so that the confidence level of the band is equal to $1 - \alpha$. The form of the two-sided hyperbolic band is illustrated in Figure 2.7. The band satisfies

$$P\{b_0 + b_1 x \in b_0 + b_1 x \pm c_{h,2} \hat{\sigma} \sqrt{v(1,x)} \forall x \in (a,A)\} = 1 - \alpha$$
Figure 2.8: The region $R_h$

$$\begin{align*}
R_h &= \bigcap_{x \in (a,A)} R_h(x)
\end{align*}$$

where $R_h = \cap_{x \in (a,A)} R_h(x)$ with

$$R_h(x) = \left\{ T : \left\{ U \left( \begin{array}{c} 1 \\ x \end{array} \right) \right\} T \| / \| U \left( \begin{array}{c} 1 \\ x \end{array} \right) \| < c_{h,2} \right\}.$$

The region $R_h(x)$ is given by a strip bounded by the 2 lines that are $c_{h,2}$ distance away from the origin and perpendicular to the vector $U(1,x)^T$. Therefore, $R_h$ is the region given by a spindle region whose angle at the vertices is $\phi$, as depicted in Figure 2.8, where $\phi$ is also the angle between $U(1,a)^T$ and $U(1,A)^T$ and is calculated as in Section 2.3.2 for the two-sided three-segment band. The confidence level of the two-sided hyperbolic band is given by the probability of $T$ in $R_h$. Let $R^*_h$ be the region that is resulted from rotating $R_h$ around the origin to the position so that the angle $\phi$ between $U(1,a)^T$ and $U(1,A)^T$ is divided into two equal halves by the $t_2$-axis, as shown in Figure 2.9. Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $R_h$ is equal to the probability of $T$ in $R^*_h$. The region $R^*_h$ is divided by the axes into four equal quarters. The top-right quarter of $R^*_h$, for instance, can be partitioned into two parts, the fan given by

$$\left\{ T : \theta_T \in \left[ \frac{\pi - \phi}{2}, \frac{\pi}{2} \right], \| T \| \leq c_{h,2} \right\}$$

and the right-angle triangle given by

$$\left\{ T : \theta_T \in \left[ 0, \frac{\pi - \phi}{2} \right], 0 \leq \left( \cos \left( \frac{\pi - \phi}{2} \right), \sin \left( \frac{\pi - \phi}{2} \right) \right) T \leq c_{h,2} \right\}.$$
Therefore, the probability of $T$ in $R_h$ is equal to four times the sum of the probabilities of $T$ in the two regions mentioned above and given by

\[
P\{T \in R_h\} = 4 \left[ \int_{0}^{\pi - \frac{\phi}{2}} \frac{1}{2\pi} \left\{ 0 \leq R_T \leq \frac{c_{h,2}}{\cos \left( \frac{\pi - \phi}{2} - \theta \right)} \right\} d\theta + \frac{\left( \frac{\phi}{2} \right)}{2\pi} P\{R_T \leq c_{h,2}\} d\theta \right] \]

where the function $F_{RT}(x)$ is defined by expression (2.3), so that the confidence level of a two-sided hyperbolic band is given by

\[
1 - \frac{\phi}{\pi} \left( 1 + \frac{c_{h,2}^2}{\nu} \right)^{-\frac{\nu}{2}} - \frac{2}{\pi} \int_{0}^{\pi - \frac{\phi}{2}} \left[ 1 + \frac{c_{h,2}^2}{\nu \sin^2(\theta + \frac{\phi}{2})} \right]^{-\frac{\nu}{2}} d\theta. \tag{2.11}
\]

There are more than one way to derive the confidence level of each of the types of confidence bands discussed in this chapter. Derivation of confidence level for one-sided confidence bands can be achieved using similar methods. Moreover, the expressions (2.6), (2.9) and (2.11) for the confidence levels of two-sided confidence bands for simple linear regression in this chapter involve computation no harder than one-dimensional integration. Next, we discuss the optimality criteria for the two-segment, three-segment and hyperbolic bands.

### 2.4 Optimality criteria for simultaneous confidence bands

An optimality criterion is a single expression that summarizes how good the entity being assessed is. The entity under a criterion is said to be optimal when it is maximized or
minimized depending on the requirements of the user. Literature on optimality criteria for experimental design is widely available and Atkinson, Donev and Tobias (2007) have provided a useful account of some of the most important ones. However, for simultaneous confidence bands, there exist fewer optimality criteria and two of them are outlined in this section. Then, the design leading to the best confidence bands under one of these criteria is derived analytically or numerically, for the two-sided two-segment, three-segment and hyperbolic bands.

2.4.1 Average width criterion

The idea of average width of a band as criterion was introduced by Gafarian (1964). It was then formalized by Naiman (1984), who defines simultaneous confidence bands for linear regression functions as \( \mu \)-optimal among a family of confidence bands, if they minimize the average width of the bands with respect to the probability measure \( \mu \) over the range of interest, among all the confidence bands in the family with equal coverage probability. For a two-sided simultaneous confidence band for an unknown regression function \( f(x) \) over the region of interest with coverage probability \( 1 - \alpha \), the points \( x_1, \ldots, x_n \) where the band will be used are random vectors which are identically and independently distributed according to the probability measure \( \mu \). Therefore, the accuracy of the resulting confidence band is proportional to \( \sum_{i=1}^n \frac{H(x)}{n} \), which converges almost surely to \( \int_x H(x)\mu \, dx \) by the strong law of large numbers, provided the integral is finite. Thus, a \( \mu \)-optimal simultaneous confidence band is the one with optimal average width accuracy. Intuitively, an optimal simultaneous confidence band under the average width criterion bounds the regression function over the range of interest as tightly as possible. This optimality criterion is used in Chapter 5 to compare between two types of confidence bands for a particular dataset.

Most work on confidence bands use the average width as optimality criterion. However, Liu and Hayter (2007) pointed out two flaws in the criterion. When comparing between confidence bands, they found that whichever band with the smaller critical constant will be deemed as the better band under the average width criterion. Moreover, the range of interest is a crucial factor when comparing bands under the criterion. For three-segment bands for instance, a three-segment band can be deemed better than another three-segment band depending on the ranges of interest that are used, although the pairs of simultaneous confidence intervals underlying the two three-segment bands are fixed.

2.4.2 Minimum area confidence set criterion

The Minimum Area Confidence Set (MACS) criterion for simultaneous confidence bands was introduced by Liu and Hayter (2007), who have defined a simultaneous confidence band for simple linear regression as optimal if the corresponding set for the linear parameters of regression model has the smallest area, among all confidence sets corresponding to simultaneous confidence bands with equal coverage probability \( 1 - \alpha \). For multiple linear regression, they use the analogous Minimum Volume Confidence Set (MVCS) criterion. Each \( 1 - \alpha \) level confidence band correspond to a \( 1 - \alpha \) level confidence set for \( \beta \) (see e.g.,
Khorasani and Milliken, 1979 and Piegorsch, 1987). Intuitively, in simple linear regression for instance, each point \((b_0, b_1)\) within a \(1 - \alpha\) level confidence set correspond to a line \(b_0 + b_1x\) lying completely within the \(1 - \alpha\) level confidence band. The smaller the area of the confidence set the fewer the candidates for the true and unknown regression line there are in the corresponding confidence band, and thus, the better the band is.

The MACS criterion is related to D-optimality in experimental design in the sense that D-optimal designs minimize the area of the \(F\) distribution confidence ellipsoid for \(b\) (see Atkinson, Donev and Tobias, 2007). This relation is outlined in Section 2.4.3. Confidence sets \(C_2, C_3\) and \(C_h\) for the two-sided two-segment, three-segment and hyperbolic bands respectively can be generated from the respective confidence regions \(R_2, R_3\) and \(R_h\) via the same linear transformation \(U^{-1}(\hat{b} - b) / \hat{\sigma}\). Subsequently, comparisons among the three types of confidence bands reduce to comparisons among the areas of \(R_2, R_3\) and \(R_h\). Using MACS criterion for simple linear regression, Liu and Hayter (2007) have shown that if the whole range of covariate is of interest, then the hyperbolic band is the recommended band among the three types of confidence bands. Furthermore, if the range of interest is finite, then a restricted hyperbolic band might be recommended, although the three-segment band can be preferable in certain cases.

2.4.3 Relation of MACS to D-optimality

D-optimality is the most intensively studied of all design criteria. It is based on the determinant of the information matrix for the design, \(\left|X^T X\right|\), which is equal to the reciprocal of the determinant of the variance-covariance matrix for the least squares estimates of the linear parameters of the model, \(\frac{1}{\left|X^T X\right|}\). Designs which maximize \(\left|X^T X\right|\) are called D-optimum designs. They minimize the content of the confidence region for the parameters \(b\) of the model. This is shown below for the model (2.1).

Since, \(\hat{b} \sim N(b, \sigma^2(X^T X)^{-1})\), we have \(\frac{1}{\sigma}(X^T X)^{\frac{1}{2}}(\hat{b} - b) \sim N(0, I_2)\) so that

\[
\begin{bmatrix}
\frac{1}{\sigma}(X^T X)^{\frac{1}{2}}(\hat{b} - b)
\end{bmatrix}^T
\begin{bmatrix}
\frac{1}{\sigma}(X^T X)^{\frac{1}{2}}(\hat{b} - b)
\end{bmatrix} \sim \chi^2_2
\]

\[
\frac{1}{\sigma^2}(\hat{b} - b)^T(X^T X)(\hat{b} - b) \sim \chi^2_2
\]

\[
\frac{(\hat{b} - b)^T(X^T X)(\hat{b} - b)}{2\sigma^2} \sim \frac{\chi^2_2}{2}
\]

\[
\frac{(\hat{b} - b)^T(X^T X)(\hat{b} - b)}{2\sigma^2} \sim \frac{\chi^2_2}{2} = F_{2,\nu}.
\]

So, \(P \left\{ (\hat{b} - b)^T(X^T X)(\hat{b} - b) \leq 2\hat{\sigma}^2 F_{2,\nu}^\alpha \right\} = 1 - \alpha\) and the region

\[
R_b = \left\{ b : (\hat{b} - b)^T(X^T X)(\hat{b} - b) \leq 2\hat{\sigma}^2 F_{2,\nu} \right\}
\]
is therefore a confidence region for \( b \) and it takes the form of an ellipse (ellipsoid for multiple linear regression). The area of \( R_b \) is given by

\[
\text{Area}(R_b) = \int \int_{R_b} 1 \, db
\]

\[
= \int \int (b - b)^T (X^T X)(b - b) \leq 2\hat{\sigma}^2 F_{2, \nu} 1 \, db
\]

\[
= \int \int (\omega^T \omega \leq 2\hat{\sigma}^2 F_{2, \nu} \left| (X^T X)^{-1} (\hat{b} - b) \right|)
\]

\[
= \frac{1}{\sqrt{|X^T X|}} \int \int (\omega^T \omega \leq 2\hat{\sigma}^2 F_{2, \nu}) \, d\omega
\]

\[
= \frac{2\pi \hat{\sigma}^2 F_{2, \nu}}{\sqrt{|X^T X|}}
\]

since \( \omega^T \omega = 2\hat{\sigma}^2 F_{2, \nu} \) defines a circle with radius \( \sqrt{2\hat{\sigma}^2 F_{2, \nu}} \). Therefore, maximizing \( \sqrt{|X^T X|} \) will minimize the area of the confidence region for \( b \). Optimality under MACS criterion is also achieved by finding the smallest area of confidence set for \( b \).

### 2.4.4 Optimal design for simultaneous confidence bands under MACS criterion

Liu and Hayter (2007) carried out comparisons among confidence bands in simple linear regression when the design and the range were given. With a chosen \( 1 - \alpha \) confidence level, they concluded that the best band over the whole line is Scheffé’s band. When the range of interest is finite, they found that whether the hyperbolic band or the three-segment band is better depends on the value of \( \phi \). When \( \phi \) is large, the hyperbolic band is better, whereas when \( \phi \) is small, the three-segment band is preferable. Moreover, they also showed that the best two-segment and three-segment bands are given by \( c_{2,2,1} = c_{2,2,2} \) and \( c_{3,2,1} = c_{3,2,2} \) respectively, that is when they have equal critical constants.

Besides using MACS criterion to compare confidence bands, the criterion can also be used to find the experimental design that leads to the minimum area of the corresponding confidence sets. This was shown by Atkinson, Donev and Tobias (2007) in their example for Scheffé’s band which is based on a regression model that holds for the whole real line. However, in most problems, a regression model holds only over a finite interval of the covariate and thus, a confidence band over a finite interval is of interest. The optimization problem for a simultaneous confidence band over a finite range of interest is therefore to find the design that minimizes the area of the corresponding confidence set.

**Two-sided two-segment bands**

The confidence set corresponding to the two-sided two-segment band, \( C_2 \), is given by

\[
C_2 = \left\{ b : U^{-1} \frac{(\hat{b} - b)}{\hat{\sigma}} \in R_2 \right\}
\]

which satisfies

\[
P\{b \in C_2\} = P\{T \in R_2\} = 1 - \alpha
\]
and can also be expressed as a linear transformation of \( R_2 \):

\[
C_2 = \{ b : b \in \hat{b} + \hat{\sigma}UR_2 \}.
\]

From Section 2.3.1, \( R_2 \) was found to be given by a rectangular region. The area of that region can be readily calculated to be \( 4c_{2,2,1}c_{2,2,2} \). Hence, the area of \( C_2 \) is given by

\[
\text{Area}(C_2) = \iint_{C_2} 1 \, db = \iint_{b \in \hat{b} + U(\hat{\sigma}R_2)} 1 \, db = \iint_{\omega \in \hat{\sigma}R_2} |U| \, d\omega \quad \text{(where } \omega = U^{-1}(\hat{b} - b)\text{)}
\]

\[
= \iint_{\rho \in R_2} \hat{\sigma}^2 |U| \, d\rho \quad \text{(where } \rho = \frac{1}{\sigma} \omega\text{)}
\]

\[
= \hat{\sigma}^2 |U| \iint_{\rho \in R_2} 1 \, d\rho \quad \text{(where } \iint_{\rho \in R_2} 1 \, d\rho \text{ is the area of } R_2\text{)}
\]

\[
= 4\hat{\sigma}^2 c_{2,2,2}c_{2,2,1}|U|.
\]

Furthermore, Liu and Hayter (2007) have shown that among all two-sided two-segment bands of the form (2.4) satisfying the confidence level requirement (2.2), the best one under MACS criterion is given uniquely by \( c_{2,2,1} = c_{2,2,2} \) and \( R_2 \) is a square. In that case,

\[
\text{Area}(C_2) = 4\hat{\sigma}^2 c_{2,2,2}^2 |U| \quad (2.12)
\]

where \( c_{2,2} = c_{2,2,1} = c_{2,2,2} \).

The critical constant \( c_{2,2} \) does not depend on the design \( X \), as shown by expression (2.5) for the confidence level of a two-sided two-segment band. Consequently, \( \text{Area}(C_2) \) monotonically increases as \( |U| \) increases, i.e. \( \text{Area}(C_2) \) monotonically decreases as \( \sqrt{|X^TX|} \) increases. The best two-sided two-segment band, under MACS criterion, is given by the smallest area of corresponding confidence set and is therefore obtained by maximizing \( \sqrt{|X^TX|} \). It can be concluded that, under MACS criterion, a D-optimal design leads to the best two-sided two-segment band.

**Two-sided three-segment bands**

The confidence set corresponding to the two-sided three-segment band, \( C_3 \), is given by

\[
C_3 = \left\{ b : U^{-1} \left( \frac{\hat{b} - b}{\hat{\sigma}} \right) \in R_3 \right\}
\]

which satisfies

\[
P\{b \in C_3\} = P\{T \in R_3\} = 1 - \alpha.
\]

From Section 2.3.2, \( R_3 \) was found to be given by a region given by a parallelogram. The area of \( R_3 \) can be easily calculated to be \( 4c_{3,2,2}c_{3,2,1}/\sin \phi \). Using a similar linear transformation as above, the area of \( C_3 \) is given by

\[
\text{Area}(C_3) = \frac{4\hat{\sigma}^2 c_{3,2,2}c_{3,2,1}|U|}{\sin \phi}.
\]
In this case, the angle $\phi$ depends on the range of interest $(a, A)$ and the design $X$. Furthermore, the critical constants depend on the angle $\phi$ and thus on the design $X$ as well through expression (2.9). Analytical minimization of $\text{Area}(C_3)$ is more complicated than that of $\text{Area}(C_2)$ and thus, numerical methods are used instead. Liu and Hayter (2007) have shown that among all two-sided three-segment bands of the form (2.7), satisfying the confidence level requirement (2.2), the best one under MACS criterion is given uniquely by $c_{3,2,1} = c_{3,2,2}$ and $R_3$ is a rhombus. In this case,

$$\text{Area}(C_3) = \frac{4\hat{\sigma}^2 c_{3,2}^2 |U|}{\sin \phi}$$  \hspace{1cm} (2.13)

where $c_{3,2} = c_{3,2,1} = c_{3,2,2}$. In Section 2.5.4, some numerical exploration is carried out to show that $\text{Area}(C_3)$ monotonically decreases as $\sqrt{|X^TX|}$ increases, so that it can be deduced that, under MACS criterion, a D-optimal design leads to the best two-sided three-segment band.

Two-sided hyperbolic bands

The confidence set corresponding to the two-sided hyperbolic band, $C_h$, is given by

$$C_h = \left\{ b : U^{-1} \frac{b - b}{\hat{\sigma}} \in R_h \right\}$$

which satisfies

$$P\{b \in C_h\} = P\{T \in R_h\} = 1 - \alpha.$$  

From section 2.3.3, $R_h$ was found to be given by a spindle region. The area of the region within the spindle can be calculated to be $c_{h,2}^2 \left[ \phi + 2 \cot \left( \frac{\phi}{2} \right) \right]$. Consequently,

$$\text{Area}(C_h) = \hat{\sigma}^2 c_{h,2}^2 |U| \left[ \phi + 2 \cot \left( \frac{\phi}{2} \right) \right].$$  \hspace{1cm} (2.14)

In this case as well, the angle $\phi$ depends on the range of interest $(a, A)$ and the design $X$. Then, the critical constants depend on the angle $\phi$ and thus on the design $X$ through expression (2.11). Minimization of $\text{Area}(C_h)$ is explored using numerical methods in Section 2.5.4 to show that $\text{Area}(C_h)$ monotonically decreases as $\sqrt{|X^TX|}$ increases so that it can be deduced that, under MACS criterion, a D-optimal design also leads to the best two-sided hyperbolic band.

2.5 Numerical examples and exploration

Atkinson, Donev and Tobias (2007) used the Desorption of Carbon Monoxide dataset as their first example of simple linear regression analysis. In the experiment, graphitized carbon was impregnated with potassium carbonate and then heated in a stream of 15% carbon dioxide in nitrogen. The yield was the total amount of carbon monoxide desorbed and it was measured against the initial potassium/carbon ratio. The results of 22 observations are shown in Table 2.1.

</table>
The mean of the amount of carbon monoxide desorbed, $\bar{x}$, is equal to 1.4068 mole/mole C %. Modelling the dataset in the form of equation (2.2), $\hat{b} = (\hat{b}_0, \hat{b}_1)^T = (-0.0380, 1.6031)$ and $\hat{\sigma} = 0.0612$

$$(X^TX)^{-1} = \begin{pmatrix} 0.1646 & -0.0847 \\ -0.0847 & 0.0602 \end{pmatrix} \quad \text{and} \quad U = \begin{pmatrix} 0.3779 & -0.1476 \\ -0.1476 & 0.1960 \end{pmatrix}.$$  

The confidence level is fixed at $1 - \alpha = 0.95$ and the range of interest is set as $(a, A) = (0, 2.5)$, so that $v(1, a) = 0.1646$, $v(1, A) = 0.1174$, $v(1, \bar{x}) = 0.0455$, $v(0, 1) = 0.0602$ and $\phi = 1.9167 \text{ rad}$. Hence, the simultaneous two-sided two-segment, three-segment and hyperbolic band and their corresponding confidence sets can be constructed for the dataset.

### 2.5.1 Two-sided two-segment band for the desorption of carbon monoxide dataset

From expression (2.6) and confidence level of $1 - \alpha = 0.95$, $c_{2,2}$ can be evaluated for the dataset to be 2.4109. Hence, expression (2.4) is used to construct the 0.95 level two-sided two-segment band for the desorption of carbon monoxide dataset, as depicted in Figure 2.10, together with the least squares regression line and the 22 observations. The corresponding region $R_2$ and the confidence set $C_2$ for $b$ are illustrated in Figure 2.11 and Figure 2.12 respectively. Hence, from equation (2.12), the area of the confidence set, $C_2$, corresponding to the two-sided two-segment band for the desorption of carbon monoxide dataset is calculated to be 0.0744 units$^2$.

### 2.5.2 Two-sided three-segment band for the desorption of carbon monoxide dataset

From expression (2.9) and confidence level of $1 - \alpha = 0.95$, $c_{3,2}$ can be evaluated for the dataset to be 2.3970. Hence, expression (2.7) is used to construct the 0.95 level two-
Figure 2.11: The region $R_2$ for desorption CO dataset

Figure 2.12: The confidence set $C_2$ for desorption CO dataset
sided three-segment band for the desorption of carbon monoxide dataset, as shown in Figure 2.13. The corresponding region $R_3$ and the confidence set $C_3$ for $b$ are illustrated in Figure 2.14 and Figure 2.15 respectively. Hence, from equation (2.13), the area of the confidence set $C_3$ for the desorption of carbon monoxide dataset is calculated to be $0.0782 \text{ units}^2$. Since this value is larger than that of the two-sided two-segment band, the two-sided two-segment band seems preferable to the two-sided three-segment band for the dataset under the MACS criterion. However, note that the two-segment band is intrinsically defined on the whole range $x \in (-\infty, \infty)$ and cannot be directly compared to the three-segment and hyperbolic bands which are defined on $x \in (a, A) = (0, 2.5)$.

### 2.5.3 Two-sided hyperbolic band for the desorption of carbon monoxide dataset

From expression (2.11) and confidence level of $1 - \alpha = 0.95$, $c_{h,2}$ can be evaluated for the dataset to be 2.5875. Hence, expression (2.10) is used to construct the 0.95 level two-sided hyperbolic band for the desorption of carbon monoxide dataset, as shown in Figure 2.16. The corresponding region $R_h$ and the confidence set $C_h$ for $b$ are illustrated in Figure 2.17 and Figure 2.18 respectively. Hence, from equation (2.14), the area of the confidence set, $C_h$, corresponding to the two-sided hyperbolic band for the desorption of carbon monoxide dataset is calculated to be $0.0712 \text{ units}^2$. Therefore, under MACS criterion, the 0.95 level two-sided hyperbolic band is the best band for the desorption of carbon monoxide dataset among the three types of 0.95 level simultaneous two-sided confidence bands.

### 2.5.4 Numerical exploration

In section 2.4.4, an analytical derivation that D-optimal designs lead to the best two-sided three-segment and hyperbolic bands under MACS criterion was not available so far.
Figure 2.14: The region $R_3$ for desorption CO dataset

Figure 2.15: The confidence set $C_3$ for desorption CO dataset
Figure 2.16: A 0.95 level two-sided hyperbolic band for desorption CO dataset

Figure 2.17: The region $R_h$ for desorption CO dataset
Subsequently, numerical methods have been used for the Desorption of Carbon Monoxide dataset, with a range of interest of \((a, A) = (0, 2.5)\) and a confidence level of \(1 - \alpha = 0.95\).

First of all, a translation in the model (2.1) is necessary to simplify the calculation of \(U\) and \(\phi\) independently. The new model is given as

\[
y_j = \beta_0 + \beta_1 (x_j - \bar{x}) + e_j
\]

where \(\beta_0 = b_0 + b_1 \bar{x}\) and \(\beta_1 = b_1\). The range of interest after translation is \((a - \bar{x}, A - \bar{x})\).

Hence,

\[
(X^T X)^{-1} = \begin{pmatrix}
\frac{1}{n} & 0 \\
0 & \frac{1}{s_{xx}}
\end{pmatrix} = \begin{pmatrix}
\frac{1}{n} & 0 \\
0 & \frac{1}{s_{xx}}
\end{pmatrix}
\]

so that

\[
U = (X^T X)^{-\frac{1}{2}} = \begin{pmatrix}
\frac{1}{\sqrt{n}} & 0 \\
0 & \frac{1}{\sqrt{s_{xx}}}
\end{pmatrix}
\]

and

\[
|U| = \frac{1}{\sqrt{|X^T X|}} = \frac{1}{\sqrt{ns_{xx}}}
\]

Hence, \(U \left( \frac{1}{a - \bar{x}} \right) = \left( \frac{1}{\sqrt{n}} \frac{(a - \bar{x})}{\sqrt{s_{xx}}} \right)^T\) and \(U \left( \frac{1}{A - \bar{x}} \right) = \left( \frac{1}{\sqrt{n}} \frac{(A - \bar{x})}{\sqrt{s_{xx}}} \right)^T\).

Moreover,

\[
\phi = \cos^{-1} \left[ \frac{\left( \frac{1}{n} + \frac{(a - \bar{x})(A - \bar{x})}{s_{xx}} \right)}{\sqrt{\left( \frac{1}{n} + \frac{(a - \bar{x})^2}{s_{xx}} \right) \left( \frac{1}{n} + \frac{(A - \bar{x})^2}{s_{xx}} \right)}} \right].
\]

For Desorption of Carbon Monoxide dataset, the value of \(\bar{x}\) is fixed. Thus, the input for numerical computation is \(s_{xx} = \sum_{i=1}^{n} (x_i - \bar{x})^2\). From \(s_{xx}\), the values of \(\phi\) can be calculated using expression (2.15). The critical constants for the two-sided three-segment band and hyperbolic band can be calculated using expressions (2.9) and (2.11) respectively.
Figure 2.19: Plot of confidence set area against $1/|U| = \sqrt{|X^T X|}$ for best 3-segment band

Hence, the areas of the corresponding confidence sets for the two-sided three-segment and hyperbolic bands can be calculated from expressions (2.13) and (2.14) respectively. Plots of these areas against $1/|U| = \sqrt{|X^T X|}$ are shown in Figure 2.19 and Figure 2.20 for the two-sided three-segment band and hyperbolic band respectively. As $\sqrt{|X^T X|}$ increases, the areas of the corresponding confidence sets are monotonically decreasing in both cases. This supports the deduction made in Section 2.4.4 that a D-optimal design leads to the best simultaneous two-sided confidence band under MACS criterion for the desorption of carbon monoxide dataset.

In the case where the value of $\bar{x}$ is not fixed, a numerical search for the area of confidence set when both $\bar{x}$ and $1/|U| = \sqrt{|X^T X|}$ vary can be carried out. For instance, a surface of the values of the area of the confidence set corresponding to the best three-segment band when $\bar{x}$ varies within $(a, A) = (0, 2.5)$ and the value of $1/|U| = \sqrt{|X^T X|}$ varies within (0, 15) is depicted in Figure 2.21. It can be observed that the area of confidence set is monotonically decreasing along the direction of the $1/|U|$-axis for a given value of $\bar{x}$.

A similar numerical search is carried out for the hyperbolic band, leading to the plot in Figure 2.22 where the area of confidence set is also monotonically decreasing along the direction of the $1/|U|$-axis for a given value of $\bar{x}$. However, this numerical result can be misleading as $\bar{x}$ and $1/|U|$ cannot be assumed to be restricted within intervals. Thus, although it can be proved analytically that D-optimal designs lead to the best two-segment bands under the MACS criterion, further research is required to show analytically that D-optimal designs lead to the best three-segment and hyperbolic bands under the MACS criterion.

In the next chapter, two new families of simultaneous confidence bands are constructed and compared in simple linear regression, within which optimal confidence bands are identified numerically.
Figure 2.20: Plot of confidence set area against $1/|U| = \sqrt{|X'X|}$ for hyperbolic band

Figure 2.21: Plot of confidence set area against $\bar{x}$ and $1/|U| = \sqrt{|X'X|}$ for best 3-segment band
Figure 2.22: Plot of confidence set area against $\bar{x}$ and $1/|U| = \sqrt{|X^T X|}$ for hyperbolic band.
Chapter 3

Searching for the best simultaneous confidence band in a particular family of confidence bands in simple linear regression

In this chapter, two families of $1 - \alpha$ level confidence bands, which include the hyperbolic band and the best three-segment band as special cases, are defined for $b_0 + b_1x$. In each family, we search the optimal confidence band under the MACS criterion. The definition of each family is based on a family of confidence sets for $b$ which is in turn defined in terms of a family of sets for $T$ via the transformation $T = U^{-1}(\hat{b} - b)/\hat{\sigma}$.

3.1 Family of inner-hyperbolic bands

This family of confidence bands is defined in terms of a family of sets $R_{\gamma_1}$ for $T$. A set $R_{\gamma_1}$ for $T$ is defined for each given angle $\gamma_1 \in [0, \phi/2]$, as depicted in Figure 3.1, in the following way. For the given $\gamma_1$, the directions $U(1, a_1)^T$ and $U(1, A_1)^T$ marked in Figure 3.1 can be determined uniquely so that $a < a_1 < A_1 < A$ and the angle between $U(1, a)^T$ and $U(1, a_1)^T$ and the angle between $U(1, A_1)^T$ and $U(1, A)^T$ are equal to $\gamma_1$. Specifically, $a < a_1 < A_1 < A$ are solved uniquely from

$$
\cos \gamma_1 = \frac{\left\| U \begin{pmatrix} 1 \\ a \end{pmatrix} \right\| \left\| U \begin{pmatrix} 1 \\ a_1 \end{pmatrix} \right\|}{\left\| U \begin{pmatrix} 1 \\ a \end{pmatrix} \right\| \left\| U \begin{pmatrix} 1 \\ a_1 \end{pmatrix} \right\|} = \frac{\left\| U \begin{pmatrix} 1 \\ A \end{pmatrix} \right\| \left\| U \begin{pmatrix} 1 \\ A_1 \end{pmatrix} \right\|}{\left\| U \begin{pmatrix} 1 \\ A \end{pmatrix} \right\| \left\| U \begin{pmatrix} 1 \\ A_1 \end{pmatrix} \right\|}.
$$

(3.1)

The set $R_{\gamma_1}$ is bounded by a segment of a circle of radius $c_{\gamma_1}/\cos \gamma_1$ centered at the origin between $U(1, a_1)^T$ and $U(1, A_1)^T$ and between $-U(1, a_1)^T$ and $-U(1, A_1)^T$. The remaining boundary of $R_{\gamma_1}$ is formed by the four line segments which are perpendicular to $U(1, a)^T$ and $U(1, A)^T$ and $c_{\gamma_1}$ distance in both directions from the origin. By the way of construction, $R_{\gamma_1}$ is uniquely determined by $c_{\gamma_1}$ for a given $\gamma_1$. We choose $c_{\gamma_1}$ such that...
Figure 3.1: The region $R_{\gamma_1}$

$P\{T \in R_{\gamma_1}\} = 1 - \alpha$. Note that, for $\gamma_1 = 0$, $R_{\gamma_1}$ is simply $R_0$ depicted in Figure 2.17 and, for $\gamma_1 = \phi/2$, $R_{\gamma_1}$ is simply $R_3$ depicted in Figure 2.14.

The confidence set for $b$ that corresponds to $R_{\gamma_1}$ is given by

$$C_{\gamma_1} = \left\{ b : U^{-1}\frac{\hat{b} - b}{\hat{\sigma}} \in R_{\gamma_1} \right\}.$$

The confidence band for $b_0 + b_1x$ that correspond to this confidence set $C_{\gamma_1}$ can be shown to be given by $\hat{b}_0 + \hat{b}_1x \pm \hat{\sigma}H_{\gamma_1}(x)$ with

$$H_{\gamma_1}(x) = \begin{cases} \frac{1}{(a_1 - a)} \left[ (x - a)c_{\gamma_1} \sqrt{v(1, a)} + (a_1 - x)c_{\gamma_1} \sqrt{v(1, a)} \right] & \text{for } \forall x \in (a, a_1) \\ \frac{c_{\gamma_1}}{\cos \gamma_1} \sqrt{v(1, x)} & \text{for } \forall x \in (a_1, A_1) \\ \frac{1}{(A - A_1)} \left[ (x - A_1)c_{\gamma_1} \sqrt{v(1, A)} + (A - x)c_{\gamma_1} \sqrt{v(1, A_1)} \right] & \text{for } \forall x \in [A_1, A]. \end{cases}$$

It is clear that when $\gamma_1$ changes within $[0, \phi/2]$ we have a family of $1 - \alpha$ level confidence bands. We call this the family of inner-hyperbolic bands. It is easy to check that, for $\gamma_1 = 0$, this band is just the hyperbolic band and, for $\gamma_1 = \phi/2$, this band is just the best three-segment band.

### 3.1.1 Confidence level of the inner-hyperbolic band

The critical constant $c_{\gamma_1}$ of the inner-hyperbolic band is determined from $P\{T \in R_{\gamma_1}\} = 1 - \alpha$. Let $R_{\gamma_1}$ be the region that is resulted from rotating $R_{\gamma_1}$ around the origin to the position so that the angle $\phi$ is divided into two equal halves by the $t_2$-axis, as depicted in Figure 3.2. Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $R_{\gamma_1}$ is equal to the probability of $T$ in $R_{\gamma_1}^*$. The region $R_{\gamma_1}$ is partitioned
into four triangles of size equal to $R_{\gamma_1, M}$ and two fans of size equal to $R_{\gamma_1, N}$, as illustrated in Figure 3.2. The probability of $T$ in $R_{\gamma_1}$ is therefore equal to the sum of twice the probability of $T$ in $R_{\gamma_1, N}$ and four times the probability of $T$ in $R_{\gamma_1, M}$.

Furthermore, the region $R_{\gamma_1, M}$ can be expressed as

$$R_{\gamma_1, M} = \left\{ T : \theta \in \left[ 0, \frac{\pi - \phi}{2} + \gamma_1 \right], \ 0 \leq \left( \cos \left( \frac{\pi - \phi}{2} \right), \sin \left( \frac{\pi - \phi}{2} \right) \right) T \leq c_{\gamma_1} \right\}$$

and so

$$P\{T \in R_{\gamma_1, M}\} = P \left\{ \theta \in \left[ 0, \frac{\pi - \phi}{2} + \gamma_1 \right], \ 0 \leq \left( \cos \left( \frac{\pi - \phi}{2} \right), \sin \left( \frac{\pi - \phi}{2} \right) \right) T \leq c_{\gamma_1} \right\}$$

$$= \int_0^{\frac{\pi - \phi}{2} + \gamma_1} \frac{1}{2\pi} P \left\{ R \leq \frac{c_{\gamma_1}}{\cos \left( \frac{\pi - \phi}{2} + \theta \right)} \right\} d\theta$$

$$= \int_0^{\frac{\pi - \phi}{2} + \gamma_1} \frac{1}{2\pi} F_R \left( \frac{c_{\gamma_1}}{\sin(\theta + \frac{\phi}{2})} \right) d\theta$$

$$= \frac{1}{2\pi} \left[ \frac{\pi - \phi}{2} + \gamma_1 \right] - \frac{1}{2\pi} \int_0^{\frac{\pi - \phi}{2} + \gamma_1} \left[ 1 + \frac{c_{\gamma_1}^2}{\nu \sin^2(\theta + \frac{\phi}{2})} \right]^{-\frac{1}{2}} d\theta.$$
and so

\[
P\{T \in R_{\gamma_1,N}\} = P\left\{ \theta \in \left[ \frac{\pi - \phi}{2} + \gamma_1, \frac{\pi + \phi}{2} - \gamma_1 \right], \|T\| \leq \frac{c_{\gamma_1}}{\cos \gamma_1} \right\}
\]

\[
= \frac{\phi - 2\gamma_1}{2\pi} P\{R \leq \frac{c_{\gamma_1}}{\cos \gamma_1} \}
\]

\[
= \frac{\phi - 2\gamma_1}{2\pi} F_R\left( \frac{c_{\gamma_1}}{\cos \gamma_1} \right)
\]

\[
= \frac{\phi - 2\gamma_1}{2\pi} \left[ 1 - \left( 1 + \frac{c_{\gamma_1}^2}{\nu \cos \gamma_1} \right)^{-\frac{\gamma}{2}} \right].
\]

Therefore, we have

\[
P\{T \in R_{\gamma_1} \} = 4P\{T \in R_{\gamma_1,M}\} + 2P\{T \in R_{\gamma_1,N}\}
\]

\[
= \frac{\phi - 2\gamma_1}{\pi} \left[ 1 - \left( 1 + \frac{c_{\gamma_1}^2}{\nu \cos \gamma_1} \right)^{-\frac{\gamma}{2}} \right] + \frac{2}{\pi} \left[ \frac{\pi - \phi}{2} + \gamma_1 \right]
\]

\[
- \frac{2}{\pi} \int_0^{\frac{\pi - \phi}{2} + \gamma_1} \left( 1 + \frac{c_{\gamma_1}^2}{\nu \sin^2(\theta + \frac{\phi}{2})} \right)^{-\frac{\gamma}{2}} d\theta.
\]

Expression (3.2) gives the confidence level of a two-sided inner-hyperbolic band for a given \(c_{\gamma_1}\), which can be used to calculate the critical constant \(c_{\gamma_1}\) for a given \(\alpha\). When \(\gamma_1 = 0\), it matches the confidence level of the two-sided hyperbolic band given by expression (2.11), whereas when \(\gamma_1 = \phi / 2\), it matches the confidence level of the best two-sided three-segment band given by expression (2.9) when \(c_{3,2,1} = c_{3,2,2}\) (see Liu and Hayter, 2007).

3.1.2 Area of confidence set corresponding to the inner-hyperbolic band

From the relationship between \(C_{\gamma_1}\) and \(R_{\gamma_1}\), similar derivation as in Section 2.4.4 can be used to show that \(\text{Area}(C_{\gamma_1}) = \sigma^2 |U| \text{Area}(R_{\gamma_1})\). Hence, from Figure 3.1, it is also clear that the region \(R_{\gamma_1}\) can be partitioned into

- two fans formed by the lines \(U(1, a_1)^T, U(1, A_1)^T\) and the boundary of the region \(R_{\gamma_1}\).
- four small right-angled triangles such as the one formed by \(U(1, a)^T, U(1, a_1)^T\) and the boundary of the region \(R_{\gamma_1}\).
- four big right-angled triangles such as the one formed by \(U(1, a)^T\), the boundary of the region \(R_{\gamma_1}\) and the line joining the vertices of the region \(R_{\gamma_1}\).

Therefore, the area of the region \(R_{\gamma_1}\) can be calculated as the sum of twice the area of one of the fans, four times the area of one of the small right-angled triangles and four times the area of one of the big right-angled triangles.

The area of one of the fans is \(\frac{1}{2} \frac{c_{\gamma_1}^2}{\cos^2 \gamma_1} (\phi - 2\gamma_1)\).

The area of one of the small right-angled triangles is \(\frac{1}{2} c_{\gamma_1}^2 \tan \gamma_1\).
The area of one of the big right-angled triangles is \( \frac{1}{2}c_{\gamma_1}^2 \cot(\frac{\phi}{2}) \).

Therefore, the area of the confidence region \( R_{\gamma_1} \) is given by

\[
\text{Area}(R_{\gamma_1}) = 2c_{\gamma_1}^2(\phi - 2\gamma_1) + 2c_{\gamma_1}^2 \tan \gamma_1 + 2c_{\gamma_1}^2 \cot(\frac{\phi}{2}).
\]

When \( \gamma_1 = 0 \), \( \text{Area}(R_{\gamma_1}) = c_{\gamma_1}^2 \left[ \phi + 2 \cot(\frac{\phi}{2}) \right] \), which is just the area of the region \( R_h \) for the hyperbolic band and when \( \gamma_1 = \frac{\phi}{2} \), \( \text{Area}(R_{\gamma_1}) = 4c_{\gamma_1}^2 / \sin \phi \), which is just the area of the region \( R_3 \) for the best three-segment band (see Liu and Hayter, 2007). Hence,

\[
\text{Area}(C_{\gamma_1}) = \sigma^2 |U| \left[ 2c_{\gamma_1}^2 \cos^2 \gamma_1(\phi - 2\gamma_1) + 2c_{\gamma_1}^2 \tan \gamma_1 + 2c_{\gamma_1}^2 \cot(\frac{\phi}{2}) \right]. \tag{3.3}
\]

### 3.1.3 Searching for the best inner-hyperbolic band

For given \( \phi \), \( \nu \) and \( \alpha \), we can numerically search for the best band in the family of \( 1 - \alpha \) level inner-hyperbolic bands by finding the angle \( \gamma_1 \in [0, \phi/2] \) that minimizes \( \text{Area}(C_{\gamma_1}) \) under the constraint \( P\{T \in R_{\gamma_1}\} = 1 - \alpha \). The dataset on the desorption of carbon monoxide from Atkinson, Donev and Tobias (2007) given in Table 3.1 is used to illustrate the numerical search. As in Section 2.5, the regression line \( b_0 + b_1x \) is to be bounded over the range of interest \( x \in (a, A) = (0, 2.5) \) by using a \( 1 - \alpha = 0.95 \) level simultaneous confidence band. The value of \( \phi \) can be calculated using equation (2.8) to be 1.9167 rad. For each value of \( \gamma_1 \in [0, \phi/2] \), the corresponding critical constant \( c_{\gamma_1} \) of the inner-hyperbolic band is computed using expression (3.2). A plot of \( c_{\gamma_1} \) against \( \gamma_1 \) is provided in Figure 3.3. Then, the corresponding area of confidence set is calculated from expression (3.3). The area of the confidence set against \( \gamma_1 \) is plotted in Figure 3.4 from which the \( \gamma_1 \in [0, \phi/2] \) that gives the MACS, i.e. the best inner-hyperbolic band, can be identified. Specifically, the area of the confidence set corresponding to the best inner-hyperbolic band is 0.07094 units², whereas those corresponding to the hyperbolic and best three-segment...
bands are 0.07120 and 0.07820 units$^2$ respectively. Furthermore, the optimal $\gamma_1 \in [0, \phi/2]$ is given by 0.3076 rad and the critical value $c_{\gamma_1} = 2.5259$. Using equation (3.1) and this optimal value of $\gamma_1$, the range $(a_1, A_1)$ is found to be (0.6601, 1.9906). The best inner-hyperbolic band is shown in Figure 3.5 together with the least squares regression line, the 22 observations and the “inner-range” $(a_1, A_1)$ as vertical dashed lines.

### 3.1.4 Comparisons

The best inner-hyperbolic band can be compared with the best three-segment band and with the hyperbolic band by looking at

$$e_{\phi,3} = \frac{\text{Area}(C_{\phi}^*)}{\text{Area}(C_3)}$$

and

$$e_{\phi,h} = \frac{\text{Area}(C_{\phi}^*)}{\text{Area}(C_h)}$$

where $C_{\phi}^*$ denotes the confidence set of the best inner-hyperbolic band. As a function of $\phi \in (0, \pi)$, $e_{\phi,3}$ is equal to one for $\phi \in (0, \phi^*)$ where $\phi^*$ is a value depending on $\nu$ and $\alpha$. Then, $e_{\phi,3}$ strictly decreases to zero for $\phi \in (\phi^*, \pi)$. Table 3.1 provides the value of $\phi^*$ for some combinations of $\nu$ and $\alpha$, while Figure 3.6 presents a typical picture of $e_{\phi,3}$.

From this, it can be concluded that the best inner-hyperbolic band is actually given by the best three-segment band for $\phi \in (0, \phi^*)$, but a more efficient band than the best three-segment band can be found for $\phi \in (\phi^*, \pi)$. The best three-segment band is very inefficient under the MACS criterion relative to the best inner-hyperbolic band when $\phi$ is close to $\pi$ since $e_{\phi,3} \rightarrow 0$ as $\phi \rightarrow \pi$.

The function $e_{\phi,h}$ first strictly decreases from one and then strictly increases and approaches one over $\phi \in (0, \pi)$. The minimum value of $e_{\phi,h}$ is only marginally smaller than one. A typical picture of $e_{\phi,h}$ is given in Figure 3.7. From this, it can be concluded that the best inner-hyperbolic band is always more efficient than the hyperbolic band under
Figure 3.5: The best 0.95 level inner-hyperbolic band for the desorption CO dataset

the MACS criterion, but the gain in efficiency of the best inner-hyperbolic band over the hyperbolic band is never large.

3.2 Family of outer-hyperbolic bands

This family of confidence bands is defined in terms of a family of sets $R_{\gamma_2}$ for $T$. For each given angle $\gamma_2 \in [0, \phi/2]$, a set $R_{\gamma_2}$ for $T$ is defined in the following way and depicted in Figure 3.8. For the given $\gamma_2$, the directions $U(1, a_1)^T$ and $U(1, A_1)^T$ in Figure 3.8 are determined uniquely so that $a < a_1 < A_1 < A$ and the angles between $U(1, a)^T$ and $U(1, a_1)^T$ and between $U(1, A)^T$ and $U(1, A_1)^T$ are equal to $\gamma_2$. The set $R_{\gamma_2}$ is bounded by a segment of a circle of radius $c_{\gamma_2}$ centered at the origin between $U(1, a_1)^T$ and $U(1, a_1)^T$, between $-U(1, a)^T$ and $-U(1, a_1)^T$, between $U(1, A_1)^T$ and $U(1, A)^T$ and between $-U(1, A)^T$ and $-U(1, A_1)^T$. The remaining boundary of $R_{\gamma_2}$ is formed by the eight line segments that are perpendicular to directions $U(1, a)^T$, $U(1, a_1)^T$, $U(1, A_1)^T$ and $U(1, A)^T$ and $c_{\gamma_2}$ distance in both directions from the origin. It is clear from this construction that $R_{\gamma_2}$ is uniquely determined by $c_{\gamma_2}$ for a given angle $\gamma_2$. We choose $c_{\gamma_2}$ such that $P\{T \in R_{\gamma_2}\} = 1 - \alpha$. Note that, for $\gamma_2 = \phi/2$, $R_{\gamma_2}$ is simply $R_{h}$ depicted in Figure 2.17 and, for $\gamma_2 = 0$, $R_{\gamma_2}$ is simply $R_3$ depicted in Figure 2.14.

The confidence set for $b$ that corresponds to $R_{\gamma_2}$ is given by

$$C_{\gamma_2} = \left\{ b : U^{-1} \frac{(\hat{b} - b)}{\sigma} \in R_{\gamma_2} \right\}.$$
The confidence band for $b_0 + b_1 x$ that correspond to this confidence set $C_{\gamma_2}$ can be shown to be given by $\hat{b}_0 + \hat{b}_1 x \pm \hat{\sigma}_{H_{\gamma_2}}(x)$ with $H_{\gamma_2}(x) = \begin{cases} c_{\gamma_2} \sqrt{v(1, x)} & \text{for } \forall x \in (a, a_1] \\ \frac{1}{(A_1 - a_1)} \left[(x - a_1)c_{\gamma_2} \sqrt{v(1, A_1)} + (A_1 - x)c_{\gamma_2} \sqrt{v(1, a_1)}\right] & \text{for } \forall x \in (a_1, A_1) \\ c_{\gamma_2} \sqrt{v(1, x)} & \text{for } \forall x \in [A_1, A]. \end{cases}$

The confidence level of the band is $1 - \alpha$ since $P\{T \in R_{\gamma_2}\} = 1 - \alpha$. It is clear that when $\gamma_2$ changes within $[0, \phi/2]$ we have a family of $1 - \alpha$ level confidence bands which is called the family of outer-hyperbolic bands. It is easy to check that, for $\gamma_2 = 0$, the band is just the best three-segment band and, for $\gamma_2 = \phi/2$, the band is just the hyperbolic band.

### 3.2.1 Confidence level of the outer-hyperbolic band

To calculate $c_{\gamma_2}$ from $P\{T \in R_{\gamma_2}\} = 1 - \alpha$, we derive an expression for $P\{T \in R_{\gamma_2}\}$. Let $R_{\gamma_2}$ be the region that is resulted from rotating $R_{\gamma_2}$ around the origin to the position so that the angle $\phi$ is divided into two equal halves by the $t_2$-axis, as depicted in Figure 3.9.

Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $R_{\gamma_2}$ is equal to the probability of $T$ in $R_{\gamma_2}^*$. The region $R_{\gamma_2}$ is partitioned into four triangles of equal size to $R_{\gamma_2,M}$, four fans of size equal to $R_{\gamma_2,N}$ and four triangles of size equal to $R_{\gamma_2,O}$, which are illustrated in Figure 3.9. The probability of $T$ in $R_{\gamma_2}$ is therefore
equal to the sum of four times the probability of $T$ in $R_{\gamma_2,O}$, four times the probability of $T$ in $R_{\gamma_2,M}$ and four times the probability of $T$ in $R_{\gamma_2,N}$.

Furthermore, the region $R_{\gamma_2,M}$ can be expressed as

$$R_{\gamma_2,M} = \left\{ T : \theta \in \left[ 0, \frac{\pi - \phi}{2} \right], \ 0 \leq \left( \cos \left( \frac{\pi - \phi}{2} \right), \sin \left( \frac{\pi - \phi}{2} \right) \right) \right\} \leq c_{\gamma_2} \right\}$$

and so

$$P\{T \in R_{\gamma_2,M}\} = P\left\{ \theta \in \left[ 0, \frac{\pi - \phi}{2} \right], \ 0 \leq \left( \cos \left( \frac{\pi - \phi}{2} \right), \sin \left( \frac{\pi - \phi}{2} \right) \right) \right\} \leq c_{\gamma_2} \right\}$$

$$= \int_{0}^{\frac{\pi - \phi}{2}} \frac{1}{2\pi} P \left\{ R \leq \cos \left( \frac{\pi - \phi}{2} - \theta \right) \right\} d\theta$$

$$= \int_{0}^{\frac{\pi - \phi}{2}} \frac{1}{2\pi} F_R \left( \frac{c_{\gamma_2}}{\sin(\theta + \frac{\phi}{2})} \right) d\theta$$

$$= \frac{1}{2\pi} \left[ \frac{\pi - \phi}{2} \right] - \frac{1}{2\pi} \int_{0}^{\frac{\pi - \phi}{2}} \left[ 1 + \frac{c_{\gamma_2}^2}{\nu \sin^2(\theta + \frac{\phi}{2})} \right]^{\frac{\nu}{2}} d\theta.$$

The region $R_{\gamma_2,N}$ can be expressed as

$$R_{\gamma_2,N} = \left\{ T : \theta \in \left[ \frac{\pi - \phi}{2}, \frac{\pi - \phi}{2} + \gamma_2 \right], \ ||T|| \leq c_{\gamma_2} \right\}$$

and so

$$P\{T \in R_{\gamma_2,N}\} = P\left\{ \theta \in \left[ \frac{\pi - \phi}{2}, \frac{\pi - \phi}{2} + \gamma_2 \right], \ ||T|| \leq c_{\gamma_2} \right\}$$

$$= \frac{\gamma_2}{2\pi} P\{R \leq c_{\gamma_2}\}$$

$$= \frac{\gamma_2}{2\pi} F_R(c_{\gamma_2})$$

$$= \frac{\gamma_2}{2\pi} \left[ 1 - \left( 1 + \frac{c_{\gamma_2}^2}{\nu^2} \right)^{-\frac{\nu}{2}} \right] .$$

The region $R_{\gamma_2,O}$ can be expressed as

$$R_{\gamma_2,O} = \left\{ T : \theta \in \left[ \frac{\pi - \phi}{2} + \gamma_2, \frac{\pi}{2} \right], \ 0 \leq \left( \sin \left( \frac{\phi - 2\gamma_2}{2} \right), \cos \left( \frac{\phi - 2\gamma_2}{2} \right) \right) \right\} \leq c_{\gamma_2} \right\}$$

and so

$$P\{T \in R_{\gamma_2,O}\} = P\left\{ \theta \in \left[ \frac{\pi - \phi}{2} + \gamma_2, \frac{\pi}{2} \right], \ 0 \leq \left( \sin \left( \frac{\phi - 2\gamma_2}{2} \right), \cos \left( \frac{\phi - 2\gamma_2}{2} \right) \right) \right\} \leq c_{\gamma_2} \right\}$$

$$= \int_{\frac{\pi - \phi}{2} + \gamma_2}^{\pi} \frac{1}{2\pi} P \left\{ R \leq \cos \left( \theta - \frac{\pi - \phi}{2} + \gamma_2 \right) \right\} d\theta$$

$$= \int_{\frac{\pi - \phi}{2} + \gamma_2}^{\pi} \frac{1}{2\pi} F_R \left( \cos \left( \theta - \left( \frac{\pi - \phi}{2} + \gamma_2 \right) \right) \right) d\theta$$

$$= \frac{\phi - 2\gamma_2}{4\pi} - \frac{1}{2\pi} \int_{\frac{\pi - \phi}{2} + \gamma_2}^{\pi} \left[ 1 + \frac{c_{\gamma_2}^2}{\nu \cos^2 \left( \theta - \left( \frac{\pi - \phi}{2} + \gamma_2 \right) \right) \right]^{-\frac{\nu}{2}} d\theta.$$

45
Therefore, we have

\[ P\{T \in R_{\gamma^2}\} = 4P\{T \in R_{\gamma^2,M}\} + 4P\{T \in R_{\gamma^2,N}\} + 4P\{T \in R_{\gamma^2,O}\} \]

\[ = \frac{2}{\pi} \left[ \frac{\pi - \phi}{2} \right] - \frac{2}{\pi} \int_0^{\frac{\pi}{2}} \left[ 1 + \frac{c^2_{\gamma^2}}{\nu \sin^2(\theta + \frac{\phi}{2})} \right] d\theta \]

\[ + \frac{2\gamma^2}{\pi} \left[ 1 - \left( 1 + \frac{c^2_{\gamma^2}}{\nu} \right) \right] + \frac{\phi - 2\gamma^2}{\pi} \]

\[ - \frac{2}{\pi} \int_{\frac{\pi}{2} - \phi + \gamma^2}^{\frac{\pi}{2}} \left[ 1 + \frac{c^2_{\gamma^2}}{\nu \cos^2\left( \theta - \left( \frac{\phi}{2} + \gamma^2 \right) \right)} \right] d\theta. \]  

Expression (3.4) gives the confidence level of a two-sided outer-hyperbolic band for a given \( c_{\gamma^2} \), which can be used to calculate the critical constant \( c_{\gamma^2} \) for a given \( \alpha \). When \( \gamma^2 = \phi/2 \), it matches the confidence level of the two-sided hyperbolic band given by expression (2.11), whereas when \( \gamma^2 = 0 \), it matches the confidence level of the best two-sided three-segment band given by expression (2.9) when \( c_{3,2,1} = c_{3,2,2} \) (see Liu and Hayter, 2007).

### 3.2.2 Area of confidence set corresponding to the outer-hyperbolic band

From the relationship between \( C_{\gamma^2} \) and \( R_{\gamma^2} \), similar derivation as in Section 2.4.4 can be used to show that \( \text{Area}(C_{\gamma^2}) = \hat{\sigma}^2 |U| \text{Area}(R_{\gamma^2}) \). Hence, from Figure 3.8, it is also clear that the region \( R_{\gamma^2} \) can be partitioned into

- four fans such as the one formed by the lines \( U(1, A_1)^T, U(1, A)^T \) and the boundary of the region \( R_{\gamma^2} \).

- four small right-angled triangles such as the one formed by \( U(1, a_1)^T \), the boundary of the region \( R_{\gamma^2} \) and the bisector of the angle \( \phi \).

- four big right-angled triangles such as the one formed by \( U(1, a)^T \), the boundary of the region \( R_{\gamma^2} \) and the line joining the two vertices that do not lie on the bisector of the angle \( \phi \).

Therefore, the area of the region \( R_{\gamma^2} \) can be calculated as the sum of four times the area of one of the sectors, four times the area of one of the small right-angled triangles and four times the area of one of the big right-angled triangles.

The area of one fan is \( \frac{1}{2} c^2_{\gamma^2} \gamma^2 \).

The area of one small right-angled triangle is \( \frac{1}{2} c^2_{\gamma^2} \tan\left( \frac{\phi}{2} - \gamma^2 \right) \).

The area of one big right-angled triangle is \( \frac{1}{2} c^2_{\gamma^2} \cot\left( \frac{\phi}{2} \right) \).

Therefore, the area of the confidence region \( R_{\gamma^2} \) is given by

\[ \text{Area}(R_{\gamma^2}) = 2c^2_{\gamma^2} \gamma^2 + 2c^2_{\gamma^2} \tan\left( \frac{\phi}{2} - \gamma^2 \right) + 2c^2_{\gamma^2} \cot\left( \frac{\phi}{2} \right). \]

When \( \gamma^2 = 0 \), \( \text{Area}(R_{\gamma^2}) = 4c^2_{\gamma^2} / \sin \phi \), which is the area of the region \( R_3 \) for the best three-segment band. When \( \gamma^2 = \phi/2 \), \( \text{Area}(R_{\gamma^2}) = c^2_{\gamma^2} \left[ \phi + 2 \cot\left( \frac{\phi}{2} \right) \right] \), which is the area
of the region $R_h$ for the hyperbolic band. Hence,

$$\text{Area}(C_{\gamma_2}) = \hat{\sigma}^2|U| \left[ 2c_{\gamma_2}^2 \gamma_2 + 2c_{\gamma_2}^2 \tan \left( \frac{\phi}{2} - \gamma_2 \right) + 2c_{\gamma_2}^2 \cot \left( \frac{\phi}{2} \right) \right]. \quad (3.5)$$

### 3.2.3 Searching for the best outer-hyperbolic band

As in Section 3.1.3, the dataset on the desorption of carbon monoxide from Atkinson, Donev and Tobias (2007) given in Table 3.1 is used to illustrate the numerical search. The regression line $b_0 + b_1 x$ is bounded over the range of interest $x \in (a, A) = (0, 2.5)$ by using a $1 - \alpha = 0.95$ level simultaneous confidence band and the value of $\phi$ can be calculated using equation (2.8) to be $1.9167 \text{ rad}$. For each value of $\gamma_2 \in [0, \phi/2]$, the corresponding critical constant $c_{\gamma_2}$ of the outer-hyperbolic band is computed using expression (3.4). The plot of $c_{\gamma_2}$ against $\gamma_2$ is plotted in Figure 3.10. Then, the corresponding area of confidence set is calculated from expression (3.5) and depicted in Figure 3.11 from which the $\gamma_2 \in [0, \phi/2]$ that gives the MACS, i.e. the best outer-hyperbolic band, can be identified. Specifically, the area of the confidence set corresponding to the best outer-hyperbolic band is $0.07117 \text{ units}^2$, the optimal $\gamma_2 \in [0, \phi/2]$ is given by $0.6200 \text{ rad}$ and the critical value $c_{\gamma_2} = 2.5765$. Using equation (3.1) and this optimal value of $\gamma_2$, the range $(a_1, A_1)$ is found to be $(1.0421, 1.6559)$. The best outer-hyperbolic band is shown in Figure 3.12.

### 3.2.4 Comparisons

For given $\phi$, $\nu$ and $\alpha$, we can search numerically the best band in the family of $1 - \alpha$ level outer-hyperbolic bands by finding the angle $\gamma_2 \in [0, \phi/2]$ that minimizes $\text{Area}(C_{\gamma_2})$ under the constraint $P\{T \in R_{\gamma_2}\} = 1 - \alpha$. We can also compare this best outer-hyperbolic band with the best three-segment band, with the hyperbolic band and with the best
Figure 3.11: Plot of $Area(C_{\gamma_2})$ against $\gamma_2$

Figure 3.12: The best 0.95 level outer-hyperbolic band for the desorption CO dataset
Figure 3.13: Plot of $E_{\phi,3}$ against $\phi$

inner-hyperbolic band by looking at

$$E_{\phi,3} = \frac{\text{Area}(C_O^*)}{\text{Area}(C_3)} , \quad E_{\phi,h} = \frac{\text{Area}(C_O^*)}{\text{Area}(C_h)} \quad \text{and} \quad E_{I,O} = \frac{\text{Area}(C_I^*)}{\text{Area}(C_O^*)}$$

where $C_O^*$ denotes the confidence set of the best outer-hyperbolic band. For $E_{\phi,3}$ and $E_{\phi,h}$, similar observations as in Section 3.1.4 are made from the numerical investigation. As a function of $\phi \in (0, \pi)$, $E_{\phi,3}$ is equal to one for $\phi \in (0, \phi^*)$ where $\phi^*$ is a value depending on $\nu$ and $\alpha$. Then, $E_{\phi,3}$ strictly decreases to zero for $\phi \in (\phi^*, \pi)$ as depicted in Figure 3.13. Table 3.2 provides the value of $\phi^*$ for some combinations of $\nu$ and $\alpha$. From this, it can be concluded that the best outer-hyperbolic band is actually given by the best three-segment band for $\phi \in (0, \phi^*)$, but a more efficient band than the best three-segment band can be found for $\phi \in (\phi^*, \pi)$.

The function $E_{\phi,h}$ first strictly decreases from one and then strictly increases and approaches one over $\phi \in (0, \pi)$. The minimum value of $E_{\phi,h}$ is again only marginally smaller than one as shown in Figure 3.14. From this, it can be concluded that the best outer-hyperbolic band is always more efficient than the hyperbolic band under the MACS criterion, but the gain in efficiency of the best outer-hyperbolic band over the hyperbolic band is small.

Finally, the function $E_{I,O}$ is always no larger than one for $\phi \in (0, \pi)$ and is only very slightly less than one for $\phi$ near 1.5 as depicted in Figure 3.15. This implies that the best inner-hyperbolic band is at least as good as the best outer-hyperbolic band but is better by only a very small amount.

3.3 Concluding remarks on the inner-hyperbolic and outer-hyperbolic bands

Two new families of simultaneous confidence bands have been introduced and it is shown how the best confidence band in each family can be identified numerically. It is observed that the best inner-hyperbolic band is always no less efficient than the best outer-hyperbolic band and so the best inner-hyperbolic band is recommended.

The best inner-hyperbolic band is in fact given by the best three-segment band when $0 < \phi \leq \phi^*$ for some $\phi^* \in (0, \pi)$ depending on $\nu$ and $\alpha$. But for $\phi^* < \phi < \pi$, the best inner-hyperbolic band can be much more efficient than the best three-segment band.

The best inner-hyperbolic band is always more efficient than the hyperbolic band, but only by a small amount. If one wants to avoid the burden of numerical search to find the best inner-hyperbolic band, then the hyperbolic band can be recommended with only a small loss of efficiency.

This concludes the work done on the construction and comparison of confidence bands in simple linear regression. In the next chapters, we turn our attention to the construction and comparison of confidence bands in multiple linear regression.

Figure 3.15: Plot of $E_{I,O}$ against $\phi$
Chapter 4

Exact simultaneous confidence bands in multiple linear regression with predictor variables constrained in an ellipsoidal region

4.1 The ellipsoidal covariate region

Chapter 2 reviewed the construction of simultaneous confidence bands for simple linear regression, when \( k = 1 \). When \( k > 1 \), there are at least two predictor variables in the model (1.1) and the region of interest \( \chi \) may assume various forms. The first part of this chapter reviews the construction of simultaneous confidence bands for the regression function

\[
x^T b = b_0 + b_1 x_1 + b_2 x_2 + \ldots + b_k x_k
\]
on an ellipsoidal region of interest \( \chi_E \). The linear regression model (1.2) is used, with the same assumptions and distributional results as in Chapter 1. Denote \( X_{(1)} \) as the \( n \times k \) matrix produced from the design matrix \( X \) by deleting the first column of 1’s from \( X \). Let \( x_{il} = \sum_{i=1}^{n} x_{il} \) be the mean of the observed values of the \( l^{th} \) predictor variable, where \( 1 \leq l \leq k \) and let \( \overline{x}_{(1)} = (x_{1}, \ldots, x_{k})^T \). Then, let \( S \) be a \( k \times k \) matrix given by

\[
S = \frac{1}{n} \left( X_{(1)} - \overline{x}_{(1)T} \right)^T \left( X_{(1)} - \overline{x}_{(1)T} \right) = \frac{1}{n} \left( X_{(1)T} X_{(1)} - n \overline{x}_{(1)} \overline{x}_{(1)T} \right)
\]
where \( 1 \) is an \( n \)-vector of 1’s. Note that \( S \) is the sample variance-covariance matrix of the \( k \) predictor variables. Hence, the region \( \chi_E \) is defined by

\[
\chi_E = \left\{ x_{(1)} : \left( x_{(1)} - \overline{x}_{(1)} \right)^T S^{-1} \left( x_{(1)} - \overline{x}_{(1)} \right) \leq r^2 \right\} \quad (4.1)
\]
where \( \mathbf{x}(1) = (x_1, \ldots, x_k)^T \) and \( r > 0 \) is a constant that determines the size of \( \chi_E \). The region is centered at \( \bar{x}(1) \) and its volume is given by

\[
\int_{\chi_E} 1 d\mathbf{x}(1) = \int_\{ (\mathbf{x}(1) - \bar{x}(1))^T S^{-1} (\mathbf{x}(1) - \bar{x}(1)) \leq r^2 \} 1 d\mathbf{x}(1) = \int_{\mathbf{\omega}_m \leq r^2} |S_+^2| d\mathbf{\omega}_m \quad \text{(where } \mathbf{\omega}_m = S_+^2 (\mathbf{x}(1) - \bar{x}(1)) \text{)}
\]

where \( \int_{\mathbf{\omega}_m \leq r^2} 1 d\mathbf{\omega}_m \) is a \((k-1)\)-sphere with radius \( r \). Therefore, \( \chi_E \) is a \((k-1)\)-sphere transformed linearly by \( S_+^2 \) to result into an ellipsoid.

Given that

\[
(X^TX)^{-1} = \begin{pmatrix} \frac{1}{n} + \bar{x}S^{-1}\bar{x}' & -\bar{x}S^{-1} \\ -S^{-1}\bar{x}' & S^{-1} \end{pmatrix}
\]

and that

\[
\mathbf{x}^T(X^TX)^{-1}\mathbf{x} = \frac{1}{n} \left[ 1 + (\mathbf{x}(1) - \bar{x}(1))^T S^{-1} (\mathbf{x}(1) - \bar{x}(1)) \right],
\]

\( \chi_E \) can also be expressed as

\[
\chi_E = \left\{ \mathbf{x}(1) : \mathbf{x}^T(X^TX)^{-1}\mathbf{x} \leq \frac{1 + r^2}{n} \right\}. \tag{4.2}
\]

Since

\[
Var(\mathbf{x}^T\mathbf{b}) = \frac{\sigma^2}{n} \left[ 1 + (\mathbf{x}(1) - \bar{x}(1))^T S^{-1} (\mathbf{x}(1) - \bar{x}(1)) \right],
\]

\( Var(\mathbf{x}^T\mathbf{b}) = \frac{\sigma^2}{n} (1 + r^2) \) for all the points \( \mathbf{x}(1) \) on the surface of the ellipsoidal region \( \chi_E \). Hence, all the points \( \mathbf{x}(1) \) on the surface of \( \chi_E \) can be regarded as of equal “distance” in terms of \( Var(\mathbf{x}^T\mathbf{b}) \) from the center \( \bar{x}(1) \). Therefore, the value of \( r^2 \) can be considered as the “range” for the region of interest \( \chi_E \).

Construction of confidence bands over regions like \( \chi_E \) has been considered by Halperin and Guirian (1968), Bohrer (1973), Casella and Strawderman (1980) and Seppanen and Uusipaikka (1992) among others. Recently, Liu and Lin (2008) provided detailed construction of exact hyperbolic confidence bands over \( \chi_E \), while Liu et al. (2009) contained details on the construction of exact constant width bands over \( \chi_E \). In this chapter, the construction of two-sided hyperbolic and constant-width bands over \( \chi_E \) are reviewed and a family of confidence bands, called the inner-hyperbolic bands, which include the hyperbolic and constant-width bands as special cases is introduced. The optimal confidence band within the family under the Minimum Volume Confidence Set (MVCS) criterion of Liu and Hayter (2007) and Liu et al. (2009) is found numerically and compared with the hyperbolic and constant width bands.

### 4.2 Preliminaries

As in Liu and Lin (2008), let \( \mathbf{z} = \sqrt{n}(1, \bar{x}(1))^T \) and let the \((k + 1) \times k\) matrix \( \mathbf{Z} \) satisfy

\[
(\mathbf{z}, \mathbf{Z})^T(X^TX)^{-1}(\mathbf{z}, \mathbf{Z}) = I_{k+1}.
\]

Then, it follows that \( \mathbf{T} = (\mathbf{z}, \mathbf{Z})^{-1}(X^TX)(\mathbf{b} - \bar{\mathbf{b}})/\hat{\sigma} \) is a
standard $t$ random vector of $k + 1$ dimensions with $\nu = n - k - 1$ degrees of freedom, denoted as $\mathbf{T} \sim t_{k+1,\nu}$. Moreover, let $\mathbf{w} = (z, Z)^T(X^T X)^{-1}\mathbf{x} = (w_1, \mathbf{w}_1)^T$, where $\mathbf{w}_1 = (w_2, w_3, \ldots, w_{k+1})^T$, so that $w_1 = z^T(X^T X)^{-1}\mathbf{x} = \frac{1}{\sqrt{n}}$, $\mathbf{w}_1 = Z^T(X^T X)^{-1}\mathbf{x}$ and $\mathbf{w}^T \mathbf{w} = \mathbf{x}^T(X^T X)^{-1}\mathbf{x} = \|\mathbf{x}\|^2$. Then, from equation (4.2), all the possible values of $\mathbf{w}_1$, determined from $\mathbf{w} = (z, Z)^T(X^T X)^{-1}\mathbf{x}$ when $\mathbf{x}_1$ varies over the region $\chi_E$, form the set

$$W_E = \left\{ \mathbf{w} : w_1 = \frac{1}{\sqrt{n}}, \|\mathbf{w}\|^2 \leq \frac{1 + r^2}{n} \right\}.$$ 

The hyperbolic band over $\chi_E$ has the form

$$\mathbf{x}^T \mathbf{b} \in \mathbf{x}^T \hat{\mathbf{b}} \pm c_h \hat{\sigma} \sqrt{\mathbf{x}^T(X^T X)^{-1} \mathbf{x}} \quad \forall \mathbf{x}_1 = (x_1, \ldots, x_k)^T \in \chi_E,$$

and its confidence level can be expressed as

$$1 - \alpha = P \left\{ \sup_{\mathbf{x}_1 \in \chi_E} \left| \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right| \sqrt{\mathbf{x}^T(X^T X)^{-1} \mathbf{x}} \right\} \leq c_h$$

$$= P \left\{ \sup_{\mathbf{x}_1 \in \chi_E} \left| \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right| \sqrt{\mathbf{x}^T(X^T X)^{-1} \mathbf{x}} \right\} \leq c_h$$

$$= P \left\{ \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right\} \leq c_h$$

where

$$V_h = \left\{ \mathbf{T} : \sup_{\mathbf{w} \in W_E} \left| \mathbf{w}^T \mathbf{T} \right| < \|\mathbf{w}\| \leq c_h \right\}.$$ 

The region $V_h$ is depicted in Figure 4.1, where the angle $\phi$ is given by

$$\phi = \cos^{-1} \left( \frac{1}{\sqrt{1 + r^2}} \right) \in (0, \frac{\pi}{2}).$$

(4.3)

The constant width band over $\chi_E$ has the form

$$\mathbf{x}^T \mathbf{b} \in \mathbf{x}^T \hat{\mathbf{b}} \pm c_c \hat{\sigma} \sqrt{(1 + r^2)/n} \quad \forall \mathbf{x}_1 = (x_1, \ldots, x_k)^T \in \chi_E,$$

and its confidence level can be expressed as

$$1 - \alpha = P \left\{ \sup_{\mathbf{x}_1 \in \chi_E} \left| \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right| \leq c_c \sqrt{(1 + r^2)/n} \right\}$$

$$= P \left\{ \sup_{\mathbf{x}_1 \in \chi_E} \left| \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right| \leq c_c \sqrt{(1 + r^2)/n} \right\}$$

$$= P \left\{ \frac{\mathbf{x}^T(\hat{\mathbf{b}} - \mathbf{b})}{\hat{\sigma}} \right\} \leq c_h$$

where

$$V_c = \left\{ \mathbf{T} : \sup_{\mathbf{w} \in W_E} \left| \mathbf{w}^T \mathbf{T} \right| \leq c_c \sqrt{(1 + r^2)/n} \right\}.$$
Figure 4.1: Cross-section of $V_h$ in the direction of $t_1$

Figure 4.2: Cross-section of $V_c$ in the direction of $t_1$
The region $V_c$ is depicted in Figure 4.2.

Polar (hyperspherical) coordinates are used for the construction of the confidence bands in this paper, as in Liu and Lin (2008) and Liu et al. (2009), as well as the calculation of the volumes of the confidence sets. The polar coordinates $(R_T, \theta_{T1}, \ldots, \theta_{Tk})^T$ of the $(k + 1)$-dimensional vector $T = (t_1, \ldots, t_{k+1})^T$ are defined by

\[
\begin{align*}
t_1 &= R_T \cos \theta_{T1} \\
t_2 &= R_T \sin \theta_{T1} \cos \theta_{T2} \\
t_3 &= R_T \sin \theta_{T1} \sin \theta_{T2} \cos \theta_{T3} \\
&\quad \vdots \\
t_k &= R_T \sin \theta_{T1} \sin \theta_{T2} \ldots \sin \theta_{Tk-1} \cos \theta_{Tk} \\
t_{k+1} &= R_T \sin \theta_{T1} \sin \theta_{T2} \ldots \sin \theta_{Tk-1} \sin \theta_{Tk}
\end{align*}
\]

where

\[
\begin{align*}
0 &\leq \theta_{T1} \leq \pi \\
0 &\leq \theta_{T2} \leq \pi \\
&\quad \vdots \\
0 &\leq \theta_{Tk-1} \leq \pi \\
0 &\leq \theta_{Tk} \leq 2\pi \\
R_T &\geq 0.
\end{align*}
\]

When $T \sim t_{k+1, \nu}$, the Jacobian of the transformation is

\[
|J| = R_T^k \sin^{k-1} \theta_{T1} \sin^{k-2} \theta_{T2} \ldots \sin \theta_{Tk-1}. \tag{4.4}
\]

Its polar coordinates are independent random variables. In particular, the marginal density of $\theta_{T1}$ is given by

\[
f(\theta) = g \sin^{k-1} \theta \quad 0 \leq \theta \leq \pi
\]

where $g$ is the normalizing constant given by $g = \frac{1}{\int_{\theta=0}^{\pi} \sin^{k-1} \theta d\theta}$ and the marginal distribution of $R_T$ is given by

\[
R_T \sim \sqrt{(k+1)F_{(k+1),\nu}}
\]

where $F_{(k+1),\nu}$ denotes an $F$ random variable that has $(k + 1)$ and $\nu$ degrees of freedom.

Let $v(R)$ denote the volume of a set $R \subset \mathbb{R}^{(k+1)}$ and let $B_{k+1}(p)$ denote the ball of radius $p$ in $\mathbb{R}^{(k+1)}$. Using the Jacobian of the transformation from cartesian to polar coordinates in (4.4), the volume of the ball, $v(B_{k+1}(p))$, can be expressed as

\[
v(B_{k+1}(p)) = \int_{R=0}^{p} \int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{\pi} \ldots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} |J| R dR d\theta_1 d\theta_2 \ldots d\theta_k = \frac{\pi^{k+1} p^{k+1}}{\Gamma\left(\frac{k+1}{2} + 1\right)}.
\]

The expression for the volume of a ball of radius $p$ is used in the following sections of this chapter to derive expressions for volumes of confidence sets corresponding to simultaneous confidence bands.
4.3 Two-sided hyperbolic band over $\chi_E$

4.3.1 Confidence level

The confidence level of the band is given by $P\{T \in V_h\}$ and the region $V_h$ can be partitioned into the regions $V_{h,1}$, $V_{h,2}$, $V_{h,3}$ and $V_{h,4}$ as depicted in Figure 4.1, where

$$V_{h,1} = \{ T : 0 < \theta T_1 \leq \phi, \, R_T \leq c_h \},$$

$$V_{h,2} = \{ T : \phi < \theta T_1 \leq \frac{\pi}{2}, \, R_T \cos(\theta T_1 - \phi) \leq c_h \},$$

$$V_{h,3} = \{ T : \frac{\pi}{2} < \theta T_1 \leq \pi - \phi, \, R_T \cos(\pi - \theta T_1 - \phi) \leq c_h \},$$

$$V_{h,4} = \{ T : \pi - \phi < \theta T_1 < \pi, \, R_T \leq c_h \}.$$

Due to the rotational invariance of the probability distribution of $T$, the probability of $T$ in $V_{h,1}$ is given by

$$P\{ T \in V_{h,1} \} = P\{ T \in V_{h,4} \} = \int_0^\phi g \sin^{k-1} \theta d\theta \cdot P\{ R_T \leq c_h \} = \int_0^\phi g \sin^{k-1} \theta d\theta \cdot F_{(k+1),\nu} \left( \frac{c_h^2}{k+1} \right).$$

Similarly,

$$P\{ T \in V_{h,2} \} = P\{ T \in V_{h,3} \} = \int_\phi^{\frac{\pi}{2}} g \sin^{k-1} \theta d\theta \cdot P\{ R_T \cos(\theta - \phi) \leq c_h \} = \int_0^{\frac{\pi}{2} - \phi} g \sin^{k-1}(\theta + \phi) \cdot F_{(k+1),\nu} \left( \frac{c_h^2}{(k+1)\cos^2 \theta} \right) d\theta.$$

The confidence level of the two-sided hyperbolic band over $\chi_E$ is therefore given by

$$1 - \alpha = \int_0^\phi 2g \sin^{k-1} \theta d\theta \cdot F_{(k+1),\nu} \left( \frac{c_h^2}{k+1} \right) + \int_0^{\frac{\pi}{2} - \phi} 2g \sin^{k-1}(\theta + \phi) \cdot F_{(k+1),\nu} \left( \frac{c_h^2}{(k+1)\cos^2 \theta} \right) d\theta. \quad (4.5)$$
4.3.2 Volume of confidence set

Using the partitioning \( V_h = V_{h,1} + V_{h,2} + V_{h,3} + V_{h,4} \), we have \( v(V_h) = v(V_{h,1}) + v(V_{h,2}) + v(V_{h,3}) + v(V_{h,4}) \), with

\[
v(V_{h,1}) = v(V_{h,4}) = \int_{R=0}^{c_h} \int_{\theta_1=0}^{\phi} \int_{\theta_2=0}^{2\pi} \cdots \int_{\theta_{k-1}=0}^{2\pi} \int_{\theta_k=0}^{2\pi} |J| dR d\theta_1 d\theta_2 d\theta_k
\]

\[
v(B_{k+1}(c_h)) / \int_{0}^{\sin^{-1} \theta_1} \sin^{-1} \theta_1 d\theta_1
\]

\[= g \int_{0}^{\phi} \sin^{-1} \theta_1 d\theta_1 \cdot v(B_{k+1}(c_h))
\]

and

\[
v(V_{h,2}) = v(V_{h,3}) = \int \int_R T \cos(\theta_1 - \phi) c_h \int_{\theta_2=0}^{2\pi} \cdots \int_{\theta_{k-1}=0}^{2\pi} \int_{\theta_k=0}^{2\pi} |J| dR d\theta_1 d\theta_2 d\theta_k
\]

\[
\phi < \theta_1 \leq \frac{\pi}{2}
\]

\[= \left\{ v(B_{k+1}(c_h)) / \int_{R=0}^{c_h} \int_{\theta_1=0}^{\phi} R^k \sin^{-1} \theta_1 dR d\theta_1 \right\}
\]

\[
\times \int \int_R T \cos(\theta_1 - \phi) c_h \int_{\theta_2=0}^{2\pi} \cdots \int_{\theta_{k-1}=0}^{2\pi} \int_{\theta_k=0}^{2\pi} |J| dR d\theta_1 d\theta_2 d\theta_k
\]

\[\phi < \theta_1 \leq \frac{\pi}{2}
\]

\[= g \int_{\theta_1=\theta}^{\frac{\pi}{2}} \sin^{-1} \theta_1 d\theta_1 \cdot v(B_{k+1}(c_h))
\]

Therefore, the volume of the confidence region \( V_h \) is given by

\[
v(V_h) = 2g \pi^{\frac{k+1}{2}} c_h \frac{1}{\Gamma \left( \frac{k+1}{2} + 1 \right)} \left[ \int_{0}^{\phi} \sin^{-1} \theta_1 d\theta_1 + \int_{\theta_1=\theta}^{\frac{\pi}{2}} \frac{\sin^{-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \right].
\]

The confidence set corresponding to the two-sided hyperbolic band over \( \chi_E, C_h \), has the form

\[C_h = \left\{ b : (z, Z)^{-1}(X^T X)(b - \bar{b})/\sigma \in V_h \right\}
\]

which satisfies

\[P\{b \in C_h\} = P\{T \in V_h\} = 1 - \alpha
\]

and can be expressed as a linear transformation of \( V_h \):

\[C_h = \left\{ b : b \in \bar{b} + \sigma(X^T X)^{-1}(z, Z)V_h \right\}.
\]

Since

\[v(C_h) = |\sigma(X^T X)^{-1}(z, Z)|v(V_h) = \sigma^{k+1} |(X^T X)^{-\frac{1}{2}}|v(V_h),
\]

the volume of \( C_h \) is given by

\[2\sigma^{k+1} |(X^T X)^{-\frac{1}{2}}|g \pi^{\frac{k+1}{2}} c_h \frac{1}{\Gamma \left( \frac{k+1}{2} + 1 \right)} \left[ \int_{0}^{\phi} \sin^{-1} \theta_1 d\theta_1 + \int_{\theta_1=\theta}^{\frac{\pi}{2}} \frac{\sin^{-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \right]. \quad (4.6)
\]
4.4 Two-sided constant width band over $\chi_E$

4.4.1 Confidence level

The confidence level of the band is given by $P\{T \in V_c\}$, where

$$V_c = \left\{ T : \sup_{w \in W_E} |w^T T| \leq c_c \sqrt{(1 + r^2)/n} \right\}.$$ 

Note that

$$\sup_{w \in W_E} |w^T T| = \sup_{w \in W_E} \left| \frac{t_1}{\sqrt{n}} w_{(1)}^T (1) \right| = \left| \frac{t_1}{\sqrt{n}} \right| + \sqrt{\frac{r^2}{n}} \| T_{(1)} \|$$

where $T = (t_1, T_{(1)})^T = (t_1, t_2, \ldots, t_{k+1})^T$. Then,

$$V_c = \left\{ T : \left| \frac{t_1}{\sqrt{n}} \right| + \sqrt{\frac{r^2}{n}} \| T_{(1)} \| \leq c_c \sqrt{(1 + r^2)/n} \right\}.$$ 

In polar coordinates,

$$V_c = \left\{ T : \frac{|t_1|}{\sqrt{n}} + \sqrt{\frac{r^2}{n}} \| T_{(1)} \| \leq c_c \sqrt{(1 + r^2)/n} \right\} = V_{c,1} + V_{c,2}$$

as depicted in Figure 4.2. The regions $V_{c,1}$ and $V_{c,2}$ can be expressed as

$$V_{c,1} = \left\{ T : 0 < \theta_{T_1} \leq \frac{\pi}{2}, R_T \cos(\theta_{T_1} - \phi) \leq c_c \right\},$$

$$V_{c,2} = \left\{ T : \frac{\pi}{2} < \theta_{T_1} < \pi, R_T \cos(\pi - \theta_{T_1} - \phi) \leq c_c \right\}.$$ 

Since $P\{T \in V_{c,1}\} = P\{T \in V_{c,2}\}$,

$$P\{T \in V_c\} = 2P\{T \in V_{c,1}\} = 2 \int_0^{\frac{\pi}{2}} g \sin^{k-1} \theta \cdot P\{R_T \cos(\theta - \phi) \leq c_c\} \, d\theta = 2 \int_0^{\frac{\pi}{2}} g \sin^{k-1} \theta \cdot F_{(k+1),\nu} \left( \frac{c_c^2}{(k+1) \cos^2(\theta - \phi)} \right) \, d\theta.$$ 

The confidence level of the two-sided constant-width band over $\chi_E$ is therefore given by

$$1 - \alpha = 2 \int_0^{\frac{\pi}{2}} g \sin^{k-1} \theta \cdot F_{(k+1),\nu} \left( \frac{c_c^2}{(k+1) \cos^2(\theta - \phi)} \right) \, d\theta. \quad (4.7)$$
4.4.2 Volume of confidence set

Using the partitioning $V_c = V_{c,1} + V_{c,2}$, we have $v(V_c) = v(V_{c,1}) + v(V_{c,2})$, with

$$v(V_{c,1}) = v(V_{c,2}) = \iint R_T \cos(\theta_1 - \phi) \leq c_c \int_{\theta_2=0}^{\pi} \cdots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} |J| dR d\theta_1 d\theta_2 d\theta_k$$

$$0 < \theta_1 \leq \frac{\pi}{2}$$

$$= \left\{ v(B_{k+1}(c_c)) / \int_{R=0}^{\sigma_c} \int_{\theta_1=0}^{\pi} R^k \sin^{k-1} \theta_1 dR d\theta_1 \right\} \times \iint R_T \cos(\theta_1 - \phi) \leq c_c \int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{\pi} \cdots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} |J| dR d\theta_1 d\theta_2 d\theta_k$$

$$0 < \theta_1 \leq \frac{\pi}{2}$$

$$= g \int_0^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \cdot v(B_{k+1}(c_c)) .$$

Therefore, the volume of the confidence region $V_c$ is given by

$$v(V_c) = 2g \frac{\pi^{\frac{k+1}{2}} c_c^{k+1}}{\Gamma \left[ \frac{k+1}{2} + 1 \right]} \int_0^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \cdot v(B_{k+1}(c_c)) .$$

The confidence set corresponding to the two-sided constant-width band over $\chi_E$, $C_c$, has the form

$$C_c = \left\{ b : (z, Z)^{-1}(X^T X)(\hat{b} - b)/\hat{\sigma} \in V_c \right\}$$

which satisfies

$$P\{b \in C_c\} = P\{T \in V_c\} = 1 - \alpha$$

and can be expressed as a linear transformation of $V_c$:

$$C_c = \left\{ b : b \in \hat{b} + \hat{\sigma}(X^T X)^{-1}(z, Z)V_c \right\} .$$

Since

$$v(C_c) = |\hat{\sigma}(X^T X)^{-1}(z, Z)| v(V_c) = \hat{\sigma}^{k+1} |(X^T X)^{-\frac{1}{2}}| v(V_c),$$

the expression for the volume of $C_c$ is given by

$$2\hat{\sigma}^{k+1} |(X^T X)^{-\frac{1}{2}}| g \frac{\pi^{\frac{k+1}{2}} c_c^{k+1}}{\Gamma \left[ \frac{k+1}{2} + 1 \right]} \int_0^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 .$$

4.5 Numerical example

The two-sided hyperbolic and constant-width bands constructed in this chapter can be used for linear regression models where $k = 1, 2$ or more than 2. When $k = 1$ or $k = 2$, graphical representation of the bands is possible. However, when $k > 2$, the only illustrations possible are cross-sections along certain planes. A portion of the Snee (1977) acetylene dataset, shown in Table 4.1, is used to illustrate the case when $k = 2$. The first two predictor variables are used, namely the reactor temperature $x_1$ and the ratio of $H_2$ to n-Heptane $x_2$ and the response variable is the conversion of n-Heptane to Acetylene $y$.

</table>

There are sixteen observations in the dataset, $n = 16$, and the fitted regression model is given by

$$y = -130.69 + 0.134x_1 + 0.351x_2,$$

with $\hat{\sigma} = 3.624$ and $R^2 = 0.92$

where $R^2$ is a popular exploratory measure of how well the model fits the observed data and can be interpreted as the proportion of the total variation in the response values that is explained by the systematic component $\mathbf{x}^T \mathbf{b}$ of the model. The ellipsoidal region $\chi_E$ is centered around the mean $\bar{x}_{(1)} = (1212.5, 12.4)^T$ and its size increases as $r$ is increased. We assume that we wish to bound the regression function $\mathbf{x}^T \mathbf{b}$ using a $1 - \alpha = 0.90$ level simultaneous confidence band over the ellipsoidal region $\chi_E$ with $r = 1.9$, so that the region of interest $\chi_E$ is given by

$$\chi_E = \{ \mathbf{x}_{(1)} : \mathbf{x}^T (X^T X)^{-1} \mathbf{x} \leq 0.288125 \}$$

as depicted in Figure 4.3 by the ellipse in the $(x_1, x_2)$-plane with $\phi = 1.0863$. Using expression (4.5), the critical constant $c_h$ is found to be 2.7229. Hence, using expression (4.6), the volume of the confidence set corresponding to the hyperbolic band over $\chi_E$ is calculated to be 0.6419 units$^3$. The two-sided hyperbolic band over $\chi_E$ is illustrated in Figure 4.3. The hyperbolic shape of the band cannot be easily distinguished from the shape of a constant width band. Therefore, cross-sections of the band along the $x_1$-direction at $x_2 = x_2$ and along the $x_2$-direction at $x_1 = x_1$ are used to show the shape of the band.
Figure 4.3: Two-sided hyperbolic band over $\chi_E$, Snee (1977) acetylene dataset

Figure 4.4 and Figure 4.5 show these respective cross-sections, where the hyperbolic form is clearer.

Similarly, using expression (4.7), the critical constant $c_c$ is found to be 2.5981. Hence, using expression (4.8), the volume of the confidence set corresponding to the constant-width band over $\chi_E$ is found to be 0.7182 units$^3$. The band, when illustrated, appears fairly similar to the band shown in Figure 4.3, but the cross-sections of the the band along the $x_1$-direction at $x_2 = x_2$ and along the $x_2$-direction at $x_1 = x_1$, depicted in Figure 4.6 and Figure 4.7, clearly show the distinction from the hyperbolic shape.

Therefore, it can be deduced that for this example, the hyperbolic band is better than the constant width band under the MVCS criterion. In the next section, we introduce the family of inner-hyperbolic bands, first discussed in Chapter 3, in multiple linear regression over the region $\chi_E$.

4.6 Family of inner-hyperbolic bands over $\chi_E$

This family of confidence bands is defined in terms of regions $V$ for $T \sim t_{k+1,\nu}$, which are in turn used to construct confidence sets for $b$. Each region $V_\gamma$ is defined in terms of an angle $\gamma \in [0, \phi]$ in the following way. The region $V_\gamma$ is given by

$$V_\gamma = V_{\gamma,1} + V_{\gamma,2} + V_{\gamma,3} + V_{\gamma,4}$$
Figure 4.4: Cross-section of the hyperbolic band along the $x_1$-direction at $x_2 = x_2$

Figure 4.5: Cross-section of the hyperbolic band along the $x_2$-direction at $x_1 = x_1$
Figure 4.6: Cross-section of the constant width band along the $x_1$-direction at $x_2 = x_2$

Figure 4.7: Cross-section of the constant width band along the $x_2$-direction at $x_1 = x_1$
where

\[ V_{\gamma,1} = \{ T : 0 < \theta_{T1} \leq \gamma, \ R_T \cos(\phi - \gamma) \leq c_\gamma \}, \]

\[ V_{\gamma,2} = \{ T : \gamma < \theta_{T1} \leq \frac{\pi}{2}, \ R_T \cos(\theta_{T1} - \phi) \leq c_\gamma \}, \]

\[ V_{\gamma,3} = \{ T : \frac{\pi}{2} < \theta_{T1} \leq \pi - \gamma, \ R_T \cos(\pi - \theta_{T1} - \phi) \leq c_\gamma \}, \]

\[ V_{\gamma,4} = \{ T : \pi - \gamma < \theta_{T1} < \pi, \ R_T \cos(\phi - \gamma) \leq c_\gamma \}. \]

The region \( V_\gamma \) is depicted in Figure 4.8. The value of the critical constant \( c_\gamma \) is chosen so that \( P\{ T \in V_\gamma \} = 1 - \alpha \) and hence \( c_\gamma \) depends on \( \gamma, \alpha, k \) and \( \nu \) and denoted by \( c_\gamma = c_\gamma(\gamma, \alpha, k, \nu) \). It is clear that when \( \gamma = \phi \), the region \( V_\gamma \) is simply the \( V_h \) depicted in Figure 4.1 corresponding to the hyperbolic band and when \( \gamma = 0 \), the region \( V_\gamma \) is simply the \( V_c \) depicted in Figure 4.2 corresponding to the constant width band. The confidence set for \( b \) corresponding to \( V_\gamma \) is given by

\[ C_\gamma = \left\{ b : (x, z)^{-1}(x^T x)(\hat{b} - b)/\hat{\sigma} \in V_\gamma \right\}, \]

which has an exact confidence level \( 1 - \alpha \).

Now we give the confidence band that corresponds to the confidence set \( C_\gamma \). For given \( \gamma \in [0, \phi] \), a value \( r_\gamma \) (0 \( \leq r_\gamma \leq r \)) can be solved uniquely from the relation

\[
\gamma = \cos^{-1}\left( \frac{1}{\sqrt{1 + r^2_\gamma}} \right). \tag{4.9}
\]
By comparing this with the equation in (4.3), it is clear that \( r_\gamma \leq r \). Now, denote \( \chi_{\gamma,E} \) as a covariate region given by

\[
\chi_{\gamma,E} = \left\{ \mathbf{x}(1) : (\mathbf{x}(1) - \bar{\mathbf{x}}(1))^T S^{-1} (\mathbf{x}(1) - \bar{\mathbf{x}}(1)) \leq r_\gamma^2 \right\},
\]

where

\[
\mathbf{x}(1) = \mathbf{x}^T (X^T X)^{-1} \mathbf{x} \leq \frac{1 + r_\gamma^2}{n}.
\]

The region \( \chi_{\gamma,E} \) is of similar shape as but smaller in size than the region \( \chi_E \). Thus, \( \chi_{\gamma,E} \) can be regarded as the “inner-region” of the region of interest \( \chi_E \). Define \( \chi_{oE} \) as the region within \( \chi_E \) and outside of \( \chi_{\gamma,E} \), given by

\[
\chi_{oE} = \left\{ \mathbf{x}(1) : \frac{1 + r_\gamma^2}{n} \leq \mathbf{x}^T (X^T X)^{-1} \mathbf{x} \leq \frac{1 + r_\gamma^2}{n} \right\}.
\]

Now, the confidence band that corresponds to the confidence set \( C_\gamma \) can be shown to be given by

\[
x^T \mathbf{b} \in x^T \mathbf{b} \pm \delta H_\gamma(\mathbf{x}) \quad \forall \mathbf{x}(1) = (x_1, \ldots, x_k)^T \in \chi_E;
\]

where

\[
H_\gamma(\mathbf{x}) = \begin{cases} 
\frac{c_\gamma}{\cos(\phi \gamma)} \sqrt{x^T (X^T X)^{-1} x} & \text{for } \forall \mathbf{x}(1) \in \chi_{\gamma,E} \\
\frac{1}{(r - r_\gamma)} \left( r - \sqrt{n x^T (X^T X)^{-1} x - 1} \right) \frac{c_\gamma}{\cos(\phi \gamma)} \sqrt{\frac{1 + r_\gamma^2}{n}} & \text{for } \forall \mathbf{x}(1) \in \chi_{oE}
\end{cases}
\]

So for each \( \gamma \in [0, \phi] \), we are able to define an exact \( 1 - \alpha \) level confidence band over \( \chi_E \). When \( \gamma \) varies over the interval \([0, \phi]\), we have a family of exact confidence bands over \( \chi_E \). In particular, \( \gamma = 0 \) corresponds to the constant width band and \( \gamma = \phi \) corresponds to the hyperbolic band.

### 4.6.1 Confidence level

Now we discuss the computation of the critical constant \( c_\gamma = c_\gamma(\gamma, \alpha, k, \nu) \). From the construction above, \( c_\gamma \) is determined from \( P\{\mathbf{T} \in V_\gamma\} = 1 - \alpha \). Hence we need to express \( P\{\mathbf{T} \in V_\gamma\} = P\{\mathbf{T} \in V_{\gamma,1}\} + P\{\mathbf{T} \in V_{\gamma,2}\} + P\{\mathbf{T} \in V_{\gamma,3}\} + P\{\mathbf{T} \in V_{\gamma,4}\} \) as a function of \( c_\gamma \). From the definitions of \( V_{\gamma,1}, V_{\gamma,2}, V_{\gamma,3} \) and \( V_{\gamma,4} \), it is clear that

\[
P\{\mathbf{T} \in V_{\gamma,1}\} = P\{\mathbf{T} \in V_{\gamma,4}\}
\]

\[
= \int_0^\gamma g \sin^{k-1} \theta \cdot P\{R \cos(\phi - \gamma) \leq c_\gamma\} \, d\theta
\]

\[
= \int_0^\gamma g \sin^{k-1} \theta \cdot F(k+1,\nu) \left( \frac{c_\gamma^2}{(k + 1) \cos^2(\phi - \gamma)} \right) \, d\theta,
\]

and

\[
P\{\mathbf{T} \in V_{\gamma,2}\} = P\{\mathbf{T} \in V_{\gamma,3}\}
\]

\[
= \int_\gamma^\pi g \sin^{k-1} \theta \cdot P\{R \cos(\theta - \phi) \leq c_\gamma\} \, d\theta
\]

\[
= \int_\gamma^\pi g \sin^{k-1} \theta \cdot F(k+1,\nu) \left( \frac{c_\gamma^2}{(k + 1) \cos^2(\theta - \phi)} \right) \, d\theta.
\]

66
Therefore, \( P\{T \in V_\gamma\} \) is given by
\[
\int_0^\gamma 2g \sin^{k-1} \theta \cdot F_{(k+1),\nu} \left( \frac{c_\gamma^2}{(k + 1) \cos^2(\phi - \gamma)} \right) d\theta \\
+ \int_\gamma^{\pi} 2g \sin^{k-1} \theta \cdot F_{(k+1),\nu} \left( \frac{c_\gamma^2}{(k + 1) \cos^2(\theta - \phi)} \right) d\theta.
\]

Expression (4.12) gives the confidence level of the inner-hyperbolic band for a given \( c_\gamma \) which can be used to calculate the critical constant \( c_\gamma \) for a given \( \alpha \). It is noteworthy that when \( \gamma = \phi \), it matches the expression for the confidence level of the hyperbolic band given in (4.5), whereas when \( \gamma = 0 \), it matches the expression for the confidence level of the constant width band given in (4.7).

### 4.6.2 Volume of confidence set

To compute the volume of the confidence set \( C_\gamma \) corresponding to the inner-hyperbolic band, we use the partitioning \( v(V_\gamma) = v(V_{\gamma,1}) + v(V_{\gamma,2}) + v(V_{\gamma,3}) + v(V_{\gamma,4}) \).

Hence, the volume of the regions \( V_{\gamma,1} \) and \( V_{\gamma,4} \) are given by
\[
v(V_{\gamma,1}) = v(V_{\gamma,4}) \\
= \int R_T \cos(\phi - \gamma) \leq c_\gamma \int_{\theta_2=0}^\pi \cdots \int_{\theta_{k-1}=0}^\pi \int_{\theta_k=0}^{2\pi} |J| dR d\theta_2 \cdots d\theta_k \]
\[0 < \theta_1 \leq \gamma\]
\[= \left\{ v(B_{k+1}(c_\gamma)) \middle| \int_{R=0}^{c_\gamma} \int_{\theta_1=0}^\pi R^k \sin^{k-1} \theta_1 dR d\theta_1 \right\} \]
\[\times \int R_T \cos(\phi - \gamma) \leq c_\gamma \int_{\theta_2=0}^\pi \cdots \int_{\theta_{k-1}=0}^\pi \int_{\theta_k=0}^{2\pi} |J| dR d\theta_2 \cdots d\theta_k \]
\[0 < \theta_1 \leq \gamma\]
\[= g \int_{\theta_1=0}^{\gamma} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\phi - \gamma)} d\theta_1 \cdot v(B_{k+1}(c_\gamma)).
\]

Similarly, the volume of the regions \( V_{\gamma,2} \) and \( V_{\gamma,3} \) are given by
\[
v(V_{\gamma,2}) = v(V_{\gamma,3}) \\
= \int R_T \cos(\theta_1 - \phi) \leq c_\gamma \int_{\theta_2=0}^\pi \cdots \int_{\theta_{k-1}=0}^\pi \int_{\theta_k=0}^{2\pi} |J| dR d\theta_2 \cdots d\theta_k \]
\[\gamma < \theta_1 \leq \frac{\pi}{2}\]
\[= g \int_{\theta_1=\gamma}^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \cdot v(B_{k+1}(c_\gamma)).
\]

Therefore, the volume of \( V_\gamma \) is given by
\[
v(V_\gamma) = 2g \left[ \int_{\theta_1=0}^{\gamma} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\phi - \gamma)} d\theta_1 + \int_{\theta_1=\gamma}^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \right] V(B_{k+1}(c_\gamma)).
\]

Note that
\[
C_\gamma = \left\{ b : (z, Z)^{-1}(X^T X)(\hat{b} - b)/\hat{\sigma} \in V_\gamma \right\}
\]
\[
= \left\{ b : b \in \hat{b} + \hat{\sigma}(X^T X)^{-1}(z, Z)V_\gamma \right\}
\]
and so

\[ v(C_\gamma) = |\hat{\sigma}(X^T X)^{-1}(z, Z)|v(V_\gamma) = \hat{\sigma}^{k+1}|(X^T X)^{-\frac{1}{2}}|v(V_\gamma). \]

Hence, the volume of \( C_\gamma \) is given by

\[ 2\hat{\sigma}^{k+1}|(X^T X)^{-\frac{1}{2}}| \pi \frac{k+1}{\Gamma\left(\frac{k+1}{2}\right)} + 1 \left[ \int_0^\gamma \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\phi - \gamma)} d\theta_1 + \int_{\gamma}^{\frac{\pi}{2}} \frac{\sin^{k-1} \theta_1}{\cos^{k+1}(\theta_1 - \phi)} d\theta_1 \right]. \]  \hspace{1cm} (4.13)

When \( \gamma = \phi \), expression (4.13) gives the volume of confidence set for the two-sided hyperbolic band in (4.6) and when \( \gamma = 0 \), it gives the volume of confidence set for the two-sided constant-width band in (4.8).

### 4.7 Searching for the best inner-hyperbolic band over \( \chi_E \)

For given \( \phi \) (or \( r \)), \( k \), \( \nu \) and \( \alpha \), we can numerically search over the family of exact \( 1 - \alpha \) level inner-hyperbolic bands for the optimal inner-hyperbolic band that minimizes \( v(C_\gamma) \) in a similar way as in Section 3.1.3. For each \( \gamma \in [0, \phi] \), we determine the critical constant \( c_\gamma \) of the inner-hyperbolic band using (4.12) and then calculate the volume of its confidence set by using (4.13). We search over \( \gamma \in [0, \phi] \) to find the \( \gamma^* \in [0, \phi] \) that gives the smallest volume of confidence set. This method is illustrated below using the Snee acetylene dataset given in Table 4.1. The first two predictor variables, namely the reactor temperature \( x_1 \) and the ratio of \( H_2 \) to n-Heptane \( x_2 \), are used to illustrate the case when \( k = 2 \). As in Section 4.5, we assume that we wish to bound the regression function \( x^T b \) using a \( 1 - \alpha = 0.90 \) level simultaneous confidence band over the ellipsoidal region \( \chi_E \) with \( r = 1.9 \), so that the region of interest \( \chi_E \) is given by

\[ \chi_E = \{ x : x^T (X^T X)^{-1} x \leq 0.288125 \} \]

as depicted in Figure 4.10 by the bigger ellipse in the \((x_1, x_2)\)-plane with \( \phi = 1.0863 \). For each value of \( \gamma \in [0, \phi] \), the corresponding critical constant \( c_\gamma \) of the inner-hyperbolic band is computed using expression (4.12). Then, the corresponding volume of confidence set is calculated from expression (4.13). The volume of the confidence set against \( \gamma \) is plotted in Figure 4.9 from which the \( \gamma \in [0, \phi] \) that gives the MVCS, i.e. the best inner-hyperbolic band, can be identified. Specifically, the volume of the confidence set corresponding to the best inner-hyperbolic band is 0.6403 units$^3$, whereas those corresponding to the hyperbolic and constant width bands are 0.6419 and 0.7182 units$^3$ respectively. Furthermore, the optimal \( \gamma^* \in [0, \phi] \) is given by 0.8332 rad with the corresponding \( r^* = 1.1005 \) from (4.9) and the critical value \( c_{\gamma^*} = 2.6874 \). The best inner-hyperbolic band is shown in Figure 4.10. The band has a hyperbolic shape within the region \( \chi_{\gamma,E} \) depicted in Figure 4.10 by the smaller ellipse in the \((x_1, x_2)\)-plane, whereas the band spans linearly in the region \( \chi_{aE} \) that is inside \( \chi_E \) but outside \( \chi_{\gamma,E} \). Unfortunately, these features cannot be easily distinguished in Figure 4.10. Therefore, cross-sectional plots, Figure 4.11 and Figure 4.12, are used to show the cross-section of the band along the \( x_1 \)-direction at \( x_2 = x_2 \) and along the
Figure 4.9: Volume of confidence set $C_\gamma$ against $\gamma$

Figure 4.10: The best 0.95 level inner-hyperbolic band over $\chi_E$, Snee acetylene dataset
Figure 4.11: Cross-section of the best inner-hyperbolic band along the $x_1$-direction at $x_2 = x_2$

Figure 4.12: Cross-section of the best inner-hyperbolic band along the $x_2$-direction at $x_1 = x_1$
Figure 4.13: Volume of confidence set $C_\gamma$ against $\gamma$ when $k = 3$

$x_2$-direction at $x_1 = x_1$ respectively, together with the respective cross-sections of the “inner-range” formed by $\chi_{\gamma,E}$. Note that if $S^{-1}$ is the block matrix given by

$$S^{-1} = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix}$$

then the inner-range along the $x_1$-direction at $x_2 = x_2$ is calculated to be $(x_1 \pm \sqrt{r_2^2/S_{11}}) = (1128.7681, 1296.2319)$. Similarly, the inner-range along the $x_2$-direction at $x_1 = x_1$ is calculated to be $(x_2 \pm \sqrt{r_2^2/S_{22}}) = (6.5634, 18.3242)$.

The third predictor variable of the Snee (1977) acetylene dataset, the contact time $x_3$, is included to the model to illustrate the numerical search when $k = 3$. The method used to bound the regression function $x^T b$ using a $1 - \alpha = 0.90$ level simultaneous confidence band over the ellipsoidal region $\chi_E$ with $r = 1.9$ is the same as for $k = 2$. In this case, the volume of confidence set varies with $\gamma$ as shown in Figure 4.13. The volume of the confidence set corresponding to the best inner-hyperbolic band is 262.6202 units$^4$, whereas those corresponding to the hyperbolic and constant width bands are 263.6401 and 281.4209 units$^4$ respectively. The optimal $\gamma^* \in [0, \phi]$ is given by 0.8245 $rad$ with the corresponding $r^* = 1.10050$ from (4.9) and the critical value $c_\gamma = 3.0500$. The best inner-hyperbolic band cannot be pictured for $k = 3$, but cross-sections of the band along predictor variables can be plotted. For instance, a cross-section of the band along the $x_1$-direction at $x_2 = x_2$ and $x_3 = x_3$ is depicted in Figure 4.14, from which it can be observed that the band bounds the regression function $x^T b$ in $[33.1325, 39.0800]$ when $x_1 = x_1$, $x_2 = x_2$ and $x_3 = x_3$. 

71
4.8 Concluding remarks on the inner-hyperbolic band over $\chi E$

A new family of simultaneous confidence bands over an ellipsoidal covariate region has been introduced and it is shown how the best confidence band in the family can be identified numerically. It is noteworthy that the expressions for the confidence level and volume of confidence set provided in this chapter are valid for any number $k$ of predictor variables. Given the confidence level and a design matrix $X$, the methods described in this chapter can be used to calculate the critical constant for the best inner-hyperbolic band and the corresponding volume of confidence set. For $k = 1$ and $k = 2$, detailed images of the band can be plotted whereas for $k > 2$, cross-sectional views of the band along the means of certain predictor variables can be generated.

The best inner-hyperbolic band can be considerably more efficient than the constant width band, as shown in the example in Section 4.7. However, the gain in efficiency in using the best inner-hyperbolic band over the hyperbolic band may be small (at least for the examples in Section 4.7). Therefore, the hyperbolic band may be recommended if one wants to avoid the numerical search to find the best inner-hyperbolic band.

In the next chapter, we consider the construction and comparison of exact confidence bands in multiple linear regression over a rectangular covariate region.
Chapter 5

Exact simultaneous confidence bands in multiple linear regression with predictor variables constrained in a rectangular region

5.1 The rectangular region

In common practice, each predictor variable in a multiple linear regression model is usually bounded and the covariate region over which a simultaneous confidence band is required is rectangular. Several authors (see e.g., Casella and Strawderman, 1980 and Naiman, 1987) have agreed that the rectangular region given by

\[ \chi_R = \{ x_{(i)} : a_i \leq x_i \leq b_i, \ i = 1, \ldots, k \}, \]

where \(-\infty \leq a_i < b_i \leq \infty\) are given constants, is one of the most useful covariate region. Construction of conservative two-sided hyperbolic confidence bands over \(\chi_R\) when \(k\) is small has been considered by Knafl, Sacks and Ylvisaker (1985), Naiman (1987, 1990) and Sun and Loader (1994) among others. More recently, a simulation-based method has been used to compute critical constants for hyperbolic bands (Liu et al., 2005a) and constant width bands (Liu et al., 2005b) for any given \(k \geq 1\) over \(\chi_R\). They expressed a critical constant as the \(1 - \alpha\) population percentile of a distribution and used the \(1 - \alpha\) sample percentile of an i.i.d. sample from this distribution as an approximation to the critical constant. Apart from simulation methods, there has been no published methods for the construction of exact simultaneous confidence bands over \(\chi_R\).

In this chapter, exact \(1 - \alpha\) level simultaneous hyperbolic and constant width bands over \(\chi_R\) are constructed by expressing the confidence level of the bands as \(k\)-dimensional integrals. The hyperbolic and constant width bands are then compared using the average width (see e.g., Naiman, 1984) and minimum volume confidence set (see e.g., Liu and Hayter, 2007 and Liu et al., 2009) optimality criteria. As in previous chapters, the key is
a transformation from cartesian to polar coordinates but a further numerical quadrature is required to implement the method.

5.2 Preliminaries

Recall from previous chapters that $U$ is the unique square root matrix of $(X^T X)^{-1}$ so that $(X^T X)^{-1} = U^2$. It immediately follows that $N = U^{-1} (\hat{b} - b)/\sigma \sim N_{k+1}(0, I)$ and $T = N/(\hat{\sigma}) = U^{-1} (\hat{b} - b)/\sigma$ is a standard multivariate t random vector of $k+1$ dimensions with $\nu = n - k - 1$ degrees of freedom (see e.g., Tong, 1990).

The transformation from cartesian to polar (hyperspherical) coordinates is similar to the transformation in Section 4.2 where the polar coordinates of the $(k+1)$-dimensional vector $T = (t_1, \ldots, t_{k+1})^T$, $(R_T, \theta_T, \ldots, \theta_{T_{k}})^T$, are defined by

\[
\begin{align*}
  t_1 &= R_T \cos \theta_T \\
  t_2 &= R_T \sin \theta_T \cos \theta_{T_2} \\
  t_3 &= R_T \sin \theta_T \sin \theta_{T_2} \cos \theta_{T_3} \\
  \vdots & \vdots \\
  t_k &= R_T \sin \theta_T \sin \theta_{T_2} \ldots \sin \theta_{T_{k-1}} \cos \theta_{T_k} \\
  t_{k+1} &= R_T \sin \theta_T \sin \theta_{T_2} \ldots \sin \theta_{T_{k-1}} \sin \theta_{T_k}
\end{align*}
\]

where

\[
\begin{align*}
  0 & \leq \theta_{T1} \leq \pi \\
  0 & \leq \theta_{T2} \leq \pi \\
  \vdots & \vdots \\
  0 & \leq \theta_{T_{k-1}} \leq \pi \\
  0 & \leq \theta_{Tk} \leq 2\pi \\
  R_T & \geq 0.
\end{align*}
\]

The joint density function of $(R_T, \theta_{T1}, \ldots, \theta_{Tk})^T$ can be found using the Jacobian of the transformation

\[
|J| = R_T^{k-1} \sin^{k-1} \theta_{T1} \sin^{k-2} \theta_{T2} \ldots \sin \theta_{T_{k-1}}.
\]

However, in this case, the marginal density of $\theta_{T_j}$ ($1 \leq j \leq k - 1$) is given by

\[
f_j(\theta) = g_j \sin^{k-1} \theta, \quad 0 \leq \theta \leq \pi \tag{5.2}
\]

where $g_j = 1/(\int_{0}^{\pi} \sin^{k-j} \theta \, d\theta)$ is the normalizing constant, the marginal density of $\theta_{Tk}$ is uniform on the interval $[0, 2\pi]$, and the marginal distribution of $R_T$ is given by

\[
R_T \sim \sqrt{(k+1) F_{(k+1), \nu}}.
\]

where $F_{(k+1), \nu}$ denotes an $F$ random variable that has $(k + 1)$ and $\nu$ degrees of freedom.
5.3 Two-sided hyperbolic band over $\chi_R$

5.3.1 Confidence level

The hyperbolic simultaneous confidence band over the region $\chi_R$ has the form

$$x^T b \in x^T b \pm c_h \hat{\sigma} \sqrt{x^T (X^T X)^{-1} x} \quad \forall x \in \{x_1, \ldots, x_k\} \in \chi_R \quad (5.3)$$

where the critical constant $c_h$ is chosen so that the confidence level of the band is $1 - \alpha$. The confidence level of the band can be expressed as

$$P \left\{ \sup_{x \in [a_i, b_i], i=1, \ldots, k} \frac{|x^T \hat{\mu} - b|}{\hat{\sigma} \sqrt{x^T (X^T X)^{-1} x}} < c_h \right\} = P \left\{ \sup_{x \in [a_i, b_i], i=1, \ldots, k} \frac{|(Ux)^T T|}{\|Ux\|} < c_h \right\} = P \left\{ \|T\| < c_h \left( \sup_{x \in [a_i, b_i], i=1, \ldots, k} \frac{|(Ux)^T T|}{\|Ux\|\|T\|} \right)^{-1} \right\} = P \{ R_T < c_h/Q_h \} \quad (5.4)$$

since $R_T = \|T\|$, where

$$Q_h = Q_h(\theta_{T1}, \ldots, \theta_{Tk}) = \sup_{x \in [a_i, b_i], i=1, \ldots, k} \frac{|(Ux)^T T|}{\|Ux\|\|T\|}.$$ 

The function $Q_h = Q_h(\theta_{T1}, \ldots, \theta_{Tk})$ depends on $(\theta_{T1}, \ldots, \theta_{Tk})^T$ only and can be quickly and accurately computed for a given $(\theta_{T1}, \ldots, \theta_{Tk})^T$ by using a simple quadratic programming method given in Liu et al. (2005a) (see Appendix A). The expression (5.4) can further be expressed as

$$\int_{\theta_1=0}^{\pi} \ldots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} P \{ R_T < c_h/Q_h | \theta_{T1} = \theta_1, \ldots, \theta_{Tk} = \theta_k \} \times f \{ \theta_{T1} = \theta_1, \ldots, \theta_{Tk} = \theta_k \} d\theta_1 \ldots d\theta_k = \int_{\theta_1=0}^{\pi} \ldots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} \frac{1}{2\pi} f_1(\theta_1) \ldots f_{k-1}(\theta_{k-1}) P \{ R_T < c_h/Q_h \} \ d\theta_1 \ldots d\theta_k \times F_{k+1, \nu} \left( c_h^2/(k+1)Q_h^2 \right) \ d\theta_1 \ldots d\theta_k. \quad (5.5)$$

Expression (5.5) gives the confidence level of the hyperbolic band and it involves only a $k$-dimensional numerical quadrature since both $Q_h$ and $F_{k+1, \nu}(\cdot)$ can be computed quickly and accurately. For an indication of typical values and time taken under different types of numerical quadrature methods, see Appendix B. In particular, for $k = 2$, the confidence level of the band is given by

$$\int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{2\pi} \frac{1}{4\pi} \sin \theta_1 F_{3, \nu} \left( \frac{c_h^2}{3(Q_h(\theta_1, \theta_2))^2} \right) \ d\theta_1 d\theta_2.$$
For $k = 3$, the confidence level is given by

$$
\int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{\pi} \int_{\theta_3=0}^{2\pi} \frac{1}{2\pi^2} \sin^2 \theta_1 \sin \theta_2 F_{4,\nu} \left( \frac{c_h^2}{4(Q_h(\theta_1, \theta_2, \theta_3))^2} \right) d\theta_1 d\theta_2 d\theta_3.
$$

The confidence level of the band for $k = 2$ and $k = 3$ can be readily and accurately calculated using numerical quadrature (e.g. the in-built functions \texttt{dblquad} and \texttt{triplequad} in Matlab). For $k > 3$, until evaluation of higher dimensional quadrature is made possible by computer software, the simulation method used in Liu et al. (2005a) is recommended.

### 5.3.2 Average width

The width of the hyperbolic band in (5.3) is equal to $2c_h \hat{\sigma} \sqrt{x^T(X^T X)^{-1}x}$ at $x_{(1)} \in \chi_R$. Hence, the average width of the band is given by

$$
AW_h = \int_{x_1=a_1}^{b_1} \ldots \int_{x_k=a_k}^{b_k} 2c_h \hat{\sigma} \sqrt{x^T(X^T X)^{-1}x} \prod_{j=1}^{k} (b_j - a_j) \ dx_1 \ldots dx_k.
$$

Expression (5.6) can be easily calculated for $k \leq 3$ by numerical quadrature, using for example the in-built functions \texttt{dblquad} and \texttt{triplequad} in Matlab. For $k > 3$, a simulation method can be used. Note that (5.6) can also be expressed as

$$
2c_h \hat{\sigma} \int_{x_{(1)} \in \chi_R} \sqrt{x^T(X^T X)^{-1}x} \ dx_{(1)} = 2c_h \hat{\sigma} E(\sqrt{x^T(X^T X)^{-1}x})
$$

where $E(\sqrt{x^T(X^T X)^{-1}x})$ is the expectation of $\sqrt{x^T(X^T X)^{-1}x}$ taken with respect to $x_{(1)} = (x_1, \ldots, x_k)^T$. Each $x_i \sim U[a_i, b_i]$, $i = 1, \ldots, k$ and $x_1, \ldots, x_k$ are independent. Therefore, $E(\sqrt{x^T(X^T X)^{-1}x})$ can be approximated by simulation as follows.

- **Step 1:** independent $x_1^a, \ldots, x_k^a$ are simulated each with $U[a_i, b_i]$ for $i = 1, \ldots, k$.
- **Step 2:** the value of $E^s = \sqrt{(1, x_1^a, \ldots, x_k^a)(X^T X)^{-1}(1, x_1^a, \ldots, x_k^a)^T}$ can be computed.
- **Step 3:** Steps 1 and 2 can be repeated $K$ times to get $E_1^s, \ldots, E_K^s$ and $\bar{E} = \frac{1}{K} \sum_{j=1}^{K} E_j^s$ can be calculated to approximate $E(\sqrt{x^T(X^T X)^{-1}x})$.

The accuracy of this approximation to the average width $AW_h$ can be gauged by the standard error given by

$$
s.e(AW_h) = 2c_h \hat{\sigma} \sqrt{\frac{1}{K} \sum_{j=1}^{K} (E_j - \bar{E})^2 / (K-1)K}.
$$

### 5.3.3 Volume of confidence set

Let

$$
V_h = \left\{ T : \sup_{x_i \in [a_i, b_i], i=1,\ldots,k} \frac{|(Ux)^T T|}{\|Ux\|} < c_h \right\}.
$$
Then, the confidence set for $b$ corresponding to the hyperbolic band in (5.3) is given by

$$C_h = \left\{ b : \sup_{x \in [a_i, b_i], i = 1, \ldots, k} \frac{|x^T(b - \hat{b})|}{\sigma \sqrt{x^T (X^T X)^{-1} x}} < c_h \right\}$$

$$= \left\{ b : U^{-1}(\hat{b} - b) / \hat{\sigma} \in V_h \right\}.$$ (5.7)

It is clear from Section 5.3.1 that

$$P\{b \in C_h\} = P\{T \in V_h\} = 1 - \alpha.$$

From expression (5.7), $C_h$ can also be expressed as

$$C_h = \{ b : b \in \hat{b} + \hat{\sigma} V_h \}.$$

Therefore, the volume of $C_h$ is given by

$$v(C_h) = |\hat{\sigma} U| v(V_h) = \hat{\sigma}^{k+1} |(X^T X)^{-1/2}| v(V_h)$$

where $v(V_h)$ denotes the volume of $V_h$ which is given by

$$v(V_h) = \int_{\theta_1=0}^{\pi} \cdots \int_{\theta_{k-1}=0}^{\pi} \int_{R=0}^{c_h/Q_h} \int_{\theta_k=0}^{\pi} |J| dR d\theta_1 d\theta_2 \cdots d\theta_k$$

$$= \int_{\theta_1=0}^{\pi} \cdots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{\pi} \frac{c_h^{k+1}}{(k+1)Q_h^k} \sin^{k-1} \theta_1 \sin^{k-2} \theta_2 \cdots \sin \theta_{k-1} dR d\theta_1 d\theta_2 \cdots d\theta_k,$$

which can be computed for $k \leq 3$ using numerical quadrature. For $k > 3$, a simulation method can be used as in Section 5.3.2. Note that $v(V_h)$ can also be expressed as

$$v(V_h) = E \left( \frac{c_h^{k+1}}{(k+1)Q_h^k} \prod_{j=1}^{k} \delta_j \right)$$

where $\frac{\sin^{k-1} \theta_1}{\delta_1}, \frac{\sin^{k-2} \theta_2}{\delta_2}, \ldots, \frac{\sin \theta_{k-1}}{\delta_{k-1}}$ and $\frac{1}{\delta_k}$ are each a density function. Hence,

$$v(V_h) = E \left( \frac{c_h^{k+1}}{(k+1)Q_h^k} \prod_{j=1}^{k} \delta_j \right)$$

where $E(1/Q_h^{k+1})$ is the expectation with respect to $(\theta_{T_1}, \ldots, \theta_{T_k})^T$ and $\prod_{j=1}^{k} \delta_j$ is given by

$$\int_{\theta_1=0}^{\pi} \cdots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{\pi} \sin^{k-1} \theta_1 \sin^{k-2} \theta_2 \cdots \sin \theta_{k-1} dR d\theta_1 d\theta_2 \cdots d\theta_k.$$

The expectation $E(1/Q_h^{k+1})$ can be approximated by simulation as follows.

- **Step 1:** a vector $N \sim N_{k+1}(0, I)$ is simulated and a vector $T = N/(\hat{\sigma})$ is simulated.
The confidence level of the band can be expressed as

where the critical constant $c$ is chosen so that the confidence level of the band is $1 - \alpha$. The confidence level of the band can be expressed as

$$P \left\{ \sup_{x_i \in [a_i, b_i], i = 1, \ldots, k} \left| \frac{x^T (\hat{b} - b)}{\sigma} \right| < c \right\}$$

$$P \left\{ \sup_{x_i \in [a_i, b_i], i = 1, \ldots, k} \left| (UX)^T T \right| < c \right\}$$

$$P \left\{ \left| T \right| < c \left( \sup_{x_i \in [a_i, b_i], i = 1, \ldots, k} \frac{\left| (UX)^T T \right|}{\left| T \right|} \right)^{-1} \right\}$$

$$P \left\{ RT < \frac{c}{Q_c} \right\} \quad (5.10)$$

where

$$Q_c = Q_c(\theta_{T1}, \ldots, \theta_{Tk}) = \sup_{x_i \in [a_i, b_i], i = 1, \ldots, k} \frac{\left| (UX)^T T \right|}{\left| T \right|}.$$ 

It is clear that $Q_c$ depends on $T$ only through $(\theta_{T1}, \ldots, \theta_{Tk})^T$. Note that $(UX)^T T / \|T\|$ is a linear function of $x_{(1)} = (x_1, \ldots, x_k)^T$ and therefore attains its maximum or minimum over $x_{(1)} \in \chi_R$ at one of the vertices of $\chi_R$. In particular, $\chi_R$ has $2^k$ vertices given by

$$L = \{ (l_1, \ldots, l_k)^T : \text{each } l_j \text{ is either } a_j \text{ or } b_j, 1 \leq j \leq k \}.$$ 

The function $Q_c$ can therefore be expressed as

$$Q_c = \sup_{x_{(1)} \in L} \frac{\left| (UX)^T T \right|}{\|T\|}$$

which can be easily computed since $L$ has only $2^k$ points. By using similar derivation as in Section 5.3.1, the confidence level expression in (5.10) can further be written as

$$\int_{\theta_1 = 0}^{\pi} \cdots \int_{\theta_{k-1} = 0}^{\pi} \int_{\theta_k = 0}^{2\pi} \frac{1}{2\pi} f_1(\theta_1) \cdots f_{k-1}(\theta_{k-1}) F_{(k+1),\nu} \left( \frac{c^2}{(k+1)Q_c^2} \right) d\theta_1 \cdots d\theta_k. \quad (5.11)$$
Expression (5.11) gives the confidence level of the constant width band and involves only a $k$-dimensional quadrature. For $k = 2$, the confidence level of the band is given by

$$
\int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{2\pi} \frac{1}{4\pi} \sin \theta_1 F_{3,\nu} \left( \frac{c_h^2}{3(Q_c(\theta_1, \theta_2))^2} \right) d\theta_1 d\theta_2.
$$

For $k = 3$, the confidence level is given by

$$
\int_{\theta_1=0}^{\pi} \int_{\theta_2=0}^{\pi} \int_{\theta_3=0}^{2\pi} \frac{1}{2\pi^2} \sin^2 \theta_1 \sin \theta_2 F_{4,\nu} \left( \frac{c_h^2}{4(Q_c(\theta_1, \theta_2, \theta_3))^2} \right) d\theta_1 d\theta_2 d\theta_3.
$$

The confidence level of the band for $k = 2$ and $k = 3$ can be readily and accurately calculated using numerical quadrature such as the in-built functions \texttt{dblquad} and \texttt{triplequad} in Matlab. For $k > 3$, the simulation method used in Liu et al. (2005b) is recommended.

### 5.4.2 Average width

The width of the constant width band in (5.9) is given by $2c_c\hat{\sigma}$ and so the average width of the band is simply given by

$$\text{AW}_c = 2c_c\hat{\sigma}. \quad (5.12)$$

### 5.4.3 Volume of confidence set

Let

$$V_c = \left\{ T : \sup_{x_i \in [a_i, b_i], i=1, \ldots, k} \left| (Ux)^T T \right| < c_c \right\}.$$

Then the confidence set for $b$ corresponding to the constant width band in (5.9) is given by

$$C_c = \left\{ b : \sup_{x_i \in [a_i, b_i], i=1, \ldots, k} \frac{|x^T(b - \hat{b})|}{\hat{\sigma}} < c_c \right\} = \left\{ b : U^{-1}(\hat{b} - b) / \hat{\sigma} \in V_c \right\}. \quad (5.13)$$

It is clear from Section 5.4.1 that

$$P\{b \in C_c\} = P\{T \in V_c\} = 1 - \alpha.$$

From expression (5.13), $C_c$ can also be expressed as

$$C_c = \{ b : b \in \hat{b} + \hat{\sigma}UV_c \}.$$

Therefore the volume of $C_c$ is given by

$$v(C_c) = |\hat{\sigma}U|v(V_c) = \hat{\sigma}^{k+1}|(X^T X)^{-\frac{1}{2}}|v(V_c) \quad (5.14)$$

where

$$v(V_c) = \int_{\theta_1=0}^{\pi} \ldots \int_{\theta_{k-1}=0}^{\pi} \int_{\theta_k=0}^{2\pi} \frac{c_h^{k+1}}{(k+1)Q_c^{k+1}} \sin^{k-1} \theta_1 \sin^{k-2} \theta_2 \ldots \sin \theta_{k-1} dR d\theta_1 d\theta_2 \ldots d\theta_k.$$
For $k = 3$, $v(V_c)$ can be quickly and accurately computed using numerical quadrature. For $k > 3$, a similar simulation method as in Section 5.3.3 can be used. Note that $v(V_c)$ can also be expressed as

$$v(V_c) = E\left(\frac{\sum_{j=1}^{k} E_j}{k+1} \right)$$

where $E(1/Q_c^{k+1})$ is the expectation with respect to $(\theta_1, \ldots, \theta_k)^T$. The expectation $E(1/Q_c^{k+1})$ can be approximated by simulation as follows.

- **Step 1**: a vector $N \sim N_{k+1}(0, I)$ is simulated and a vector $T = N/(\sigma_n)$ is simulated.
- **Step 2**: the polar coordinates $(\theta_1, \ldots, \theta_k)^T$ of $T$ are obtained and the value of $E^s = (1/Q_c(\theta_1, \ldots, \theta_k)^{k+1})$ can be computed.
- **Step 3**: Steps 1 and 2 can be repeated $K$ times to get $E_1^s, \ldots, E_K^s$ and $\bar{E} = \frac{1}{K} \sum_{j=1}^{K} E_j^s$ can be calculated to approximate $E(1/Q_c^{k+1})$.

The accuracy of this approximation to the volume of confidence set $v(C_c)$ can be gauged by the standard error given by

$$s.e(v(C_c)) = \hat{\sigma}^{k+1}|(X^T X)^{-\frac{1}{2}}| \frac{c_h^{k+1}}{k+1} \prod_{j=1}^{k} \delta_j \sqrt{\sum_{j=1}^{K} (E_j - \bar{E})^2 / (K-1)K}.$$  

### 5.5 Numerical examples

A portion of the Snee (1977) acetylene dataset in Table 4.1 is used to illustrate the results derived above when $k = 2$. The first two predictor variables, the reactor temperature $x_1$ and the ratio of $H_2$ to n-Heptane $x_2$ are considered in this example and the third predictor variable, the contact time $x_3$, is excluded. For the resulting design matrix $X$, the observed range $[a_1,b_1] \times [a_2, b_2] = [1100, 1300] \times [5.3, 23]$ and a confidence level of $1 - \alpha = 0.95$, the critical constant for the hyperbolic band is calculated using expression (5.5) to be $c_h = 3.1153$ and the 0.95 confidence level hyperbolic band over $[a_1, b_1] \times [a_2, b_2] = [1100, 1300] \times [5.3, 23]$ is depicted in Figure 5.1. In addition, the regions $V_h$ is also depicted in Figure 5.2. The average width for the hyperbolic band is found to be $AW_h = 8.9338$ from expression (5.6) and the volume of confidence set corresponding to the hyperbolic band is found to be $v(C_h) = 0.2507$ units$^3$ from expression (5.8). The
Figure 5.1: The 0.95 level hyperbolic band, Snee (1977) acetylene dataset, $k=2$

Figure 5.2: The region $V_h$
The simulation method has also been used to provide a means of comparison to the method of numerical quadrature. With \(1 \times 10^5\) simulations, the average width for the hyperbolic band is found to be \(AW_h = 8.9356\) with a standard error \(s.e(AW_h) = 6.6366 \times 10^{-3}\) and the volume of confidence set corresponding to the hyperbolic band is found to be \(v(C_h) = 0.2508\) units\(^3\) with a standard error \(s.e(v(C_h)) = 1.3334 \times 10^{-4}\).

Similarly, the critical constant for the constant width band is calculated using expression (5.11) to be \(c_c = 1.6984\) and the 0.95 confidence level constant width band over the same covariate region is depicted in Figure 5.3. The region \(V_c\) is also depicted in Figure 5.4. The average width for the constant width band is found to be \(AW_c = 12.3099\) from expression (5.12) and the volume of confidence set corresponding to the constant width band is found to be \(v(C_c) = 0.3513\) units\(^3\) from expression (5.14). With \(1 \times 10^5\) simulations, the volume of confidence set corresponding to the constant width band is found to be \(v(C_c) = 0.3527\) units\(^3\) with a standard error \(s.e(v(C_c)) = 7.1608 \times 10^{-4}\) using the simulation method. Therefore, the hyperbolic band is better than the constant width band over the the observed range \([a_1, b_1] \times [a_2, b_2] \times [a_3, b_3] = [1100, 1300] \times [5.3, 23] \times [0.0115, 0.098]\) and a confidence level of \(1 - \alpha = 0.95\), the critical constants for the hyperbolic and constant width bands are found to be \(c_h = 3.5286\) and \(c_c = 6.1614\) respectively. Their respective
Figure 5.4: The region $V_c$

Figure 5.5: A superposition of regions $V_h$ and $V_c$
average widths are calculated to be $AW_h = 25.116$ and $AW_c = 46.421$. Finally, their respective volumes of confidence sets are found to be $v(C_h) = 187.203 \text{ units}^4$ and $v(C_c) = 5055.053 \text{ units}^4$. When the simulation method is used, with $1 \times 10^5$ simulations, the average width for the hyperbolic band is found to be $AW_h = 25.0614$ with a standard error $s.e(AW_h) = 0.0419$ and the volumes of confidence sets corresponding to the hyperbolic and constant width bands are found to be $v(C_h) = 187.121 \text{ units}^4$ with a standard error $s.e(v(C_h)) = 0.1240$ and $v(C_c) = 4963.546 \text{ units}^4$ with a standard error $s.e(v(C_c)) = 38.2770$ respectively. Therefore, it is clear that the hyperbolic band is more efficient than the constant width band for this example under both the average width and minimum volume confidence set optimality criteria.

5.6 Concluding remarks on exact confidence bands over $\chi_R$

For linear regression with $k(>1)$ over a rectangular covariate region, only conservative or approximate methods are available in the statistical literature. A general formula for the construction of exact hyperbolic and constant width bands for $k$ covariates restricted in intervals is provided in this chapter. The key is a transformation from cartesian to polar coordinates as in the previous chapters. To implement the method, a numerical quadrature is also necessary. For $k = 2$ and $k = 3$, the confidence levels, the required critical constants, average widths and volumes of confidence sets can be quickly and exactly computed using numerical quadrature such as the built-in functions `dblquad` and `triplequad` in Matlab. For the computation of confidence levels when $k > 3$, simulations methods are provided by Liu et al. (2005a) and Liu et al. (2005b). For the computation of average widths and volumes of confidence sets when $k > 3$, similar simulation methods have been proposed here.

The computations for the hyperbolic band are typically more time-consuming than for the constant width band due to the quadratic programming method pointed out in Section 5.3.1. However, for a rectangular covariate region $\chi_R$, the hyperbolic band can be considerably more efficient than the constant width band under both the average width and minimum volume confidence set optimality criteria (at least for the examples in Section 5.5) and is therefore the recommended band.
Chapter 6

Conclusions and Future work

Simultaneous confidence bands in linear regression analysis are useful tools that can be applied to many aspects of real life. This thesis is a concise account of the construction of exact two-sided confidence bands in linear regression. The key method used involves a transformation from cartesian to polar coordinates and expressing the confidence level of a band as a $k$-dimensional integration. In simple linear regression, it has been shown analytically that a D-optimal design leads to the the best two-segment band under the MACS criterion. Attempts by numerical search to show that D-optimal designs also lead to the best three-segment and hyperbolic bands have been made. Two new families of confidence bands, called the inner-hyperbolic bands and the outer-hyperbolic bands, have been introduced and it has been shown that the best confidence band in each family can be more efficient than the best three-segment and hyperbolic bands. It is also shown numerically that the best inner-hyperbolic band is always as good as or better than the best outer-hyperbolic band. Thus, the inner-hyperbolic family of confidence bands has also been constructed in multiple linear regression over an ellipsoidal covariate region where comparisons to the hyperbolic and constant width bands have led to similar results as in simple linear regression. In the case where the predictor variables are constrained in a rectangular covariate region, a method to construct and compare between exact two-sided hyperbolic and constant width bands has been proposed for the first time.

Moreover, this thesis also points out some problems that might be of interest for future research. Although only exact two-sided confidence bands have been considered, exact one-sided bands can also be constructed using similar methods. However, the confidence sets for one-sided bands require a different interpretation as they have infinite volumes and recently, Liu et al. (2009) have provided a method to overcome this issue. Hence, the analytical deduction that D-optimal designs lead to the best three-segment and hyperbolic bands under the MACS criterion is yet to be considered. Although the numerical exploration in Section 2.5 gives some insight into how the area of confidence set varies with the mean of the predictor variable $\bar{x}$ and $\sqrt{|X^TX|}$, it is not a complete answer. The relationship between $\bar{x}$ and $\sqrt{|X^TX|}$ is more complicated and thus the region over which Figure 2.21 and Figure 2.22 are plotted is not appropriate. In addition, due to its desirable properties, the outer-hyperbolic family of confidence bands can also be constructed in
multiple linear regression over an ellipsoidal covariate region, although the best band in the family is not as efficient as the best inner-hyperbolic band under the MACS criterion. When the covariate region is rectangular, although expressions for the construction of exact confidence bands have been provided, their computation is possible for up to three predictor variables so far. For \( k > 3 \), simulation methods are recommended until further improvement in software or future research make exact construction of confidence bands over a rectangular covariate region possible. Matlab scripts and functions have been used for all the numerical computation and illustrative plots throughout the thesis and are available upon request for the reader to explore the methods and results of the thesis. Making the computer codes available in other statistical software could also be useful future work.

The most important contribution of this thesis is the method to construct and compare exact two-sided confidence bands over a rectangular covariate region. Before this, only methods to construct conservative confidence bands or simulation methods were available in linear regression.

The hyperbolic band is a safe recommendation with only a small loss of efficiency and being generally easy to construct. However, a small increase in efficiency can have a big importance in real life situations and thus another important contribution of the thesis is the introduction of the family of inner-hyperbolic bands for simple linear regression and multiple linear regression over ellipsoidal regions and the method to construct the best band within the family.

88
Appendix A

Computation of

\[ Q_h = Q_h(\theta_{T_1}, \ldots, \theta_{T_k}) \]

We need to compute the function

\[ Q_h = \sup_{x_i \in [a_i, b_i], i=1, \ldots, k} \frac{|(Ux)^T T|}{|Ux||T|} \]

where \( L(U, \chi_R) \) forms a cone spanned by the vectors given by \( Ux = u_0 + l_1 u_1 + \ldots + l_k u_k \), where each \( l_j \) is either \( a_j \) or \( b_j \), \( 1 \leq j \leq k \). Let \( \psi(t, U, \chi_R) \) denote the projection of \( t \in \mathbb{R}^{k+1} \) to the cone \( L(U, \chi_R) \). Then, it follows from Naiman (1987, Theorem 2.1) that

\[ Q_h = \max \{ ||\psi(T/||T||, U, \chi_R)||, ||\psi(-T/||T||, U, \chi_R)|| \} \]

Note that \( \psi(t, U, \chi_R) \) solves the problem

\[ \min_{v \in L(U, \chi_R)} ||v - t||^2 \]

which is equivalent to minimizing the function

\[ \frac{1}{2} v^T v - t^T v, \]

subject to \( v \in L(U, \chi_R) \). From the definition of \( L(U, \chi_R) \), \( v \in L(U, \chi_R) \) implies that \( v = \lambda Ux \) or equivalently

\[ U^{-1}v = \lambda x = (\lambda, \lambda x_1, \ldots, \lambda x_k)^T \]

for \( x_{(1)} \in \chi_R \) and \( \lambda \geq 0 \).

Let the vector \( q_j \in \mathbb{R}^{k+1} \) have the \( j^{th} \) element equal to 1 with all the remaining elements equal to 0. Then, \( q_j^T U^{-1}v = \lambda \geq 0 \) and \( a_j \leq q_j^T U^{-1}v/q_j^T U^{-1}v \leq b_j \) for \( j = 1, \ldots, k \) or equivalently

\[ -q_j^T U^{-1}v \leq 0 \]

\[ (q_j^T - b_j q_1^T) U^{-1}v \leq 0 \text{ for } j = 1, \ldots, k \]

\[ (a_j q_1^T - q_j^T) U^{-1}v \leq 0 \text{ for } j = 1, \ldots, k. \]
These constraints can be expressed as $Av \leq 0$ where the $(2k + 1) \times (k + 1)$ matrix $A$ is given by

$$
\begin{pmatrix}
(q_2^T - b_1q_1^T)U^{-1} \\
(a_1q_1^T - q_2^T)U^{-1} \\
\vdots \\
(q_{k+1}^T - b_kq_1^T)U^{-1} \\
(a_kq_1^T - q_{k+1}^T)U^{-1} \\
-q_1U^{-1}
\end{pmatrix}.
$$

The problem of minimizing the function $\frac{1}{2}v^Tv - t^Tv$ under the constraints $Av \leq 0$ is a standard quadratic programming problem that can be solved numerically (e.g. by Matlab using the in-built function `quadprog(H,f,A,b)`). Therefore, given $\theta_{T_1}, \ldots, \theta_{T_k}$, the unit vector $T/\|T\|$ can be calculated and the value of $\psi(T/\|T\|, U, \chi_R)$ can be computed using, for example, `quadprog(H,f,A,b)` in Matlab to obtain $Q_h$. 
Appendix B

Matlab computation values and times for confidence bands over $\chi_R$

The computation of critical constants, average widths and volume of confidence sets for a given dataset (or design matrix $X$) and confidence level $1 - \alpha$ in the thesis have been performed on Matlab. The scripts and functions produced for the contents of this thesis are all available upon request.

The computations involved in Chapter 5 are typically time consuming. Computations for the previous chapters are very quick and accurate, taking usually less than a minute. However, the implementation of the quadratic programming problem in the numerical quadratures in Chapter 5 is more computer intensive. Tables B.1 - B.6 show the computation values and time taken for various methods of numerical quadrature and tolerance levels for $k = 2$ and $k = 3$ on a dual core PC, 3.0GHz, 3.0GHz, 1.99 GB RAM. Two levels of tolerances are used, $tol = 10^{-6}$ and $tol = 10^{-3}$. The parameter $tol$ refers to the absolute error tolerance used in Matlab for numerical quadratures and the default value is $tol = 10^{-6}$. Larger values of $tol$ result in fewer function evaluations and faster computation, but less accurate results. Two methods of numerical quadratures are used, $quad$ and $quadl$. The function $quad$ refers to a recursive adaptive Simpson quadrature used in Matlab. It is most efficient for low accuracies with non-smooth integrands. The function $quadl$ refers to a recursive adaptive Lobatto quadrature used in Matlab. It is more efficient than $quad$ for high accuracies with smooth integrands.

The time taken for the computation of confidence levels given the values of critical constants and $\alpha$ are typically one tenth of the time taken for computation of critical constants given confidence levels and $\alpha$. Furthermore, simulation methods are typically more computer intensive than the $k$-dimensional quadrature methods used in Chapter 5. Specifically, for $k = 2$, 100000 simulations took a total time taken of 470 seconds to attain a value of $v(C_h) = 0.2508$. 100000 simulations took a total time taken of 13 seconds to attain a value of $v(C_c) = 0.3527$. For $k = 3$, 100000 simulations took a total time taken of 600 seconds to attain a value of $v(C_h) = 187.121$. 100000 simulations took a total time taken of 15 seconds to attain a value of $v(C_c) = 4963.546$.
