A SEMISMOOTH NEWTON METHOD FOR THE NEAREST EUCLIDEAN DISTANCE MATRIX PROBLEM

HOU-DUO QI

Abstract. The Nearest Euclidean distance matrix problem (NEDM) is a fundamental computational problem in applications such as multidimensional scaling and molecular conformation from nuclear magnetic resonance data in computational chemistry. Especially in the latter application, the problem is often large scale with the number of atoms ranging from a few hundreds to a few thousands. In this paper, we introduce a semismooth Newton method that solves the dual problem of (NEDM). We prove that the method is quadratically convergent. We then present an application of the Newton method to NEDM with $H$-weights. We demonstrate the superior performance of the Newton method over existing methods including the latest quadratic semi-definite programming solver. This research also opens a new avenue towards efficient solution methods for the molecular embedding problem.

Key words. Euclidean distance matrix, semismooth Newton method, quadratic convergence.

AMS subject classifications. 49M45, 90C25, 90C33

1. Introduction. Finding a Euclidean distance matrix (EDM) that is nearest to a given data matrix is a fundamental computational problem in many applications including multidimensional scaling and molecular conformation from nuclear magnetic resonance data in computational chemistry. We do not intend to give a detailed account of the importance of EDM to the two applications. Instead we simply point to the excellent books [6] by Borg and Gronenen and [12] by Cox and Cox for the former application, and [13] by Crippen and Havel and the review paper [36] (and references therein) by Neumaier for the latter. We also refer to a recent paper [16] by Fang and O'Leary for algorithmic comparisons on different approaches to the EDM completion problem, which is closely related to ours. For its link to the latest development in semidefinite programming, see Dattorro [14], Toh [45] and a recent survey [30] by Krislock and Wolkowicz. The purpose of this paper is to propose an efficient Newton method for large scale problems of this type. Below we describe the problem in detail and review some existing methods that motivate our research.

Let $S^n$ denote the space of $n 	imes n$ symmetric matrices equipped with the standard inner product $\langle A, B \rangle = \text{trace}(AB)$ for $A, B \in S^n$. Let $\| \cdot \|$ denote the induced Frobenius norm. Let $S^n_+$ denote the cone of positive semidefinite matrices in $S^n$ (often abbreviated as $X \succeq 0$ for $X \in S^n_+$). The so-called hollow subspace $S^n_h$ is defined by

$$ S^n_h := \{ A \in S^n : \text{diag}(A) = 0 \}, $$

where diag$(A)$ is the vector formed by the diagonal elements of $A$. A matrix $D$ is an EDM if $D \in S^n_h$ and there exist points $p_1, \ldots, p_n$ in $\mathbb{R}^r$ ($r \leq n - 1$) such that $D_{ij} = \|p_i - p_j\|^2$ for $i, j = 1, \ldots, n$. $\mathbb{R}^r$ is often referred to as the embedding space and $r$ is the embedding dimension when it is the smallest such $r$. It is well-known that a matrix $D \in S^n_h$ is an EDM if, and only if,

$$ J(-D)J \succeq 0 \quad \text{and} \quad J := I - ee^T/n, $$

where $e$ is the $n$-dimensional vector of ones. This equation expresses the condition that $J(-D)J$ is positive semidefinite, which is the dual of the EDM problem. The dual problem of the EDM problem is to minimize

$$ \text{trace}(P) $$

subject to

$$ J(-P)J \succeq 0 \quad \text{and} \quad J := I - ee^T/n, $$

where $P$ is a symmetric matrix. The semismooth Newton method introduced in this paper is an efficient way to solve this dual problem.
where \( I \) (or \( I_n \) when the indication of dimension is needed) is the identity matrix in \( S_n \) and \( e \) is the vector of all ones in \( \mathbb{R}^n \). The origin of this result can be traced back to Schoenberg [42] and an independent work [47] by Young and Householder. See also Gower [23] for a nice derivation of (1). The corresponding embedding dimension \( r = \text{rank}(JDJ) \leq n - 1 \).

It is noted that the matrix \( J \), when treated as an operator, is the orthogonal projection onto the subspace \( e^\perp := \{ x \in \mathbb{R}^n : e^T x = 0 \} \). The characterization (1) simply means that \( D \) is an EDM if, and only if, \( D \in S_n^h \) and \( D \) is negative semidefinite on the subspace \( e^\perp \):

\[
-D \in K^+_n := \{ A \in S^n : x^T Ax \geq 0, \ x \in e^\perp \}. \tag{2}
\]

It is easy to check whether a given data matrix \( D \) is an EDM via (1). If it is not, then it is often possible to calculate the nearest EDM to \( D \) in order to retain as much distance information as possible. This problem can be formulated as the following nearest Euclidean distance matrix problem:

\[
v_p := \min \| D - X \|^2/2 \quad \text{s.t.} \quad X \in S^h_n \cap K^+_n. \tag{3}
\]

Given \((-D)\) being used in (2), the matrix \( D \) in (3) should be \(-D\). This change of sign has been widely adopted to reformulate (3) (see, e.g., [19, 17, 1]) and it reminds us that the objective is to minimize a distance. The widely used \( H \)-weighted version (see [1]) is defined as

\[
\min \| H \circ (D - X) \|^2/2 \quad \text{s.t.} \quad X \in S^h_n \cap K^+_n, \tag{4}
\]

where \( H \in S^n \) is nonnegative (i.e., \( H_{ij} \geq 0 \)) and \( \circ \) denotes the Hadamard product among matrices. In practice, the magnitude of \( H_{ij} \) reflects the level of accuracy of the corresponding distance \( D_{ij} \). The \( H \)-weighted problem is much more difficult to solve than (3) (Note: (4) reduces to (3) when \( H = E \), the matrix of all ones in \( S^n \)). Our main purpose of this paper is to develop a fast convergent Newton method for (3) and then apply it to (4). Below we conduct a brief literature review on both problems.

Problem (3) has been the main subject of several important papers. We first note that the feasible region is the intersection of the subspace \( S^h_n \) and the closed convex cone \( K^+_n \). Hence, alternating projection methods of Dykstra-Han type [15, 24] are a choice. In fact, one such method, called Modified Alternating Projection (MAP), was studied by Glunt et al. [19]. The same method was independently studied by Gaffke and Mathar [17], but based on a different projection formula on \( K^+_n \) (see (15) and (17)). However, MAP does not apply to (4) unless \( H = E \). Problem (3) (and in general (4)) can also be solved by Semi-Definite Programming (SDP) initiated by Alfakih et al. [1] (see also [2]). We note that the dimension of \( S^h_n \) is \( n(n-1)/2 \), as is the dimension of the cone \( E^n \) of the Euclidean distance matrices, where \( E^n := S^h_n \cap (-K^+_n) \) (see [26]). Alfakih et al. introduced their interesting linear mapping: \( K_V : S^{n-1}_+ \mapsto E^n \) defined by

\[
K_V(X) = \text{diag}(VXV^T)e^T + e\text{diag}(VXV^T)^T - 2VXV^T,
\]

where \( V \in \mathbb{R}^{n \times (n-1)} \) satisfies \( V^TV = I_{n-1} \) and \( V^Te = 0 \). Then (4) is equivalent to the problem

\[
\min \| H \circ (K_V(X) - D) \|^2/2 \quad \text{s.t.} \quad X \in S^{n-1}_+ \tag{5}
\]
It is also interesting to note that the mapping $K_V$ also allows for Slater's condition to hold (see [1, Cor. 2]). Alfakih et al. studied an interior point method based on the Gauss-Newton direction. This method can only deal with problems with size up to a hundred. Problem (5) (possibly with more linear equalities) was one of the major convex quadratic SDPs studied by Toh [45], where problem size $n$ can be a couple of thousands. Other linear mappings instead of $K_V$ can be used, see [30]. Generally speaking, specific transformations must take place before SDP can be applied to (3) and (4). Such transformations aim to shift the difficulty of handling the cone $K_n^+$ to new objective functions defined on $S_n^+$. The cost is that the new objective function is more complicated than the original distance function. Those transformations tend to destroy the nice geometric properties of $K_n^+$, which we will take advantage of to develop our Newton method.

Problem (3) also plays a very important role in solving the embedding problem. In multidimensional scaling, the given matrix $D$ is often called dissimilarity and the embedding dimension $r$ should be small; whereas in molecular conformation $D$ is often called a predistance matrix (i.e., $D \in S_n^h$ with $D_{ij} \geq 0$ for all $i, j$) and the embedding dimension $r = 3$. Therefore, the well-known embedding problem [20] is to find the nearest EDM with a low embedding dimension $r$:

$$\min \| D - X \|^2 / 2 \quad \text{s.t.} \quad X \in S_n^h \cap K_n^+ \quad \text{and} \quad \text{rank}(JXJ) \leq r.$$ (6)

Compared to (3), problem (6) is nonconvex and is hence extremely difficult to solve. The Phase I of the two-phase methods in [20] for (6) is to find the optimal solution of (3) and modify it as a starting point for the Phase II method. Further developments can be found in [21, 22]. Fast algorithms for (3) are crucial in those applications.

Problem (3) also bears a remarkable resemblance to the nearest correlation matrix problem:

$$\min \| C - X \|^2 / 2 \quad \text{s.t.} \quad \text{diag}(X) = e, \ X \in S_n^+,$$ (7)

where $C \in S^n$ is given. The constraints define the set of all $n \times n$ correlation matrices. Higham [28] studied this problem and made it widely accessible to the community of numerical analysis and optimization. The subsequent research, all trying to design efficient algorithms for (7), include (to just name a few) [31, 8, 38, 45, 7]. An important approach emerged from those studies is the Lagrangian dual approach, which was first applied to (7) by Malick [31] and Boyd and Xiao [8]. The dual approach was then studied by Qi and Sun [38] to design what is now known as one of the most efficient methods for (7): the semismooth Newton method. The link of the dual approach to that used in the classical computational mathematics (see e.g., [34, 33]) was well discussed in [38]. This class of research also motivated our research in this paper.

When applied to problem (3), the Lagrangian dual problem (in the form of minimization) becomes (see [33, Thm. 2.2] and also [41, 31, 8]):

$$v_d := \min_{y \in \mathbb{R}^n} \theta(y) := \| \Pi_{K_n^+}(D + \text{Diag}(y)) \|^2 / 2 - \| D \|^2 / 2,$$ (8)

where $\Pi_{K_n^+} (\cdot)$ denotes the orthogonal projection onto the closed convex cone $K_n^+$ and $\text{Diag}(y)$ is the diagonal matrix with $y$ being its diagonal. Function $\theta(\cdot)$ is just once continuously differentiable, but convex. Furthermore, (8) must have an optimal solution (see Prop. 2.1), which can be found through the first-order optimality condition:

$$F(y) := \nabla \theta(y) = \text{diag}\left( \Pi_{K_n^+}(D + \text{Diag}(y)) \right) = 0.$$ (9)
If \( y \) is a solution of (9), then
\[
X := \Pi_{K_n^+} (D + \text{Diag}(y)),
\]
is the optimal solution of (3). This follows from the zero duality gap result (i.e., \( v_p = -v_d \)), which can be easily proved via writing down the Lagrangian function of (3) and using Prop. 2.1. Hence, it is enough to solve the dual problem and it is relatively easy to solve as it is defined in \( \mathbb{R}^n \) rather than in the significantly larger space \( \mathbb{R}^n \).

It follows from the projection formula (17) of Gaffke and Mathar that \( F(y) \) is strongly semismooth\(^1\) because it is a composition of linear mappings and \( \Pi_{S^n_+} (\cdot) \) (the orthogonal projection onto \( S^n_+ \)) and \( \Pi_{S^n_+} (\cdot) \) is known to be strongly semismooth [44, 9]. Now it becomes natural to develop the semismooth Newton method: Given \( y^0 \in \mathbb{R}^n \) and let \( k := 0 \). Compute \( V_k \in \partial F(y^k) \) and
\[
y^{k+1} = y^k - V_k^{-1} F(y^k), \quad k = 0, 1, 2, \ldots
\]
Since \( F \) is the gradient of \( \theta \), \( \partial F \) is often called the generalized Hessian of \( \theta \), denoted by \( \partial^2 \theta(y) \). We refer to [38, Sect. 3] for a detailed development of (11) for (7). The above arguments leading to the Newton method (11) for (3) fail to hold for the \( H \)-weighted problem (4) because the projection onto \( K_n^+ \) under the \( H \)-weights does not have an analytical formula. It is already very difficult to calculate the projection under the \( H \)-weights, let alone computing its generalized Jacobian.

Therefore, our main tasks in this paper are (i) to address the quadratic convergence of (11); (ii) to demonstrate its superior numerical performance, especially on large scale problems; and (iii) to apply it to the \( H \)-weighted problem (4).

The paper is organized as follows. The first two sections below are devoted to the Newton method (11). In the next section, we include some notation and technical results. One of the results states that problem (3) is constraint nondegenerate (Thm. 2.3). A characterization of the constraint nondegeneracy (Prop. 2.4) generalizes the corresponding result in SDP of Alizadeh et al. [3]. In Sect. 3, we conduct quadratic convergence analysis of the Newton method (11). The main result is Thm. 3.3, which says that every matrix in the generalized Jacobian of \( F \) at the optimal solution is positive definite. This result then leads to the quadratic convergence result Thm. 3.5. Sect. 4 includes an application of the Newton method to the \( H \)-weighted problem (4). We report our numerical results in Sect. 5 and we conclude the paper in Sect. 6 by discussing the use of the Newton method in future research.

2. Preliminaries. In this section, we first list most of notations used in this paper and review two formulae of \( \Pi_{K_n^+} \). We finish this section by establishing two results on the existence of an optimal dual solution for (8) and constraint nondegeneracy of (3).

2.1. Notation and Two Formulae of \( \Pi_{K_n^+} \). Apart from \( S^n, S^n_+, S^n_0, K_n^+, J, \text{diag} \) and \( \text{Diag} \) we have mentioned in the introduction, we also need the following

\(^1\)A (locally) Lipschitz function \( \Phi : \mathbb{R}^m \to \mathbb{R}^l \) is said to be strongly semismooth at \( x \in \mathbb{R}^m \) if (i) \( \Phi \) is directionally differentiable at \( x \), and (ii) for any \( V \in \partial \Phi(x + h) \),
\[
\Phi(x + h) - \Phi(x) - Vh = o(\|h\|^2), \quad h \in \mathbb{R}^m,
\]
where \( \partial \Phi(x) \) denotes the generalized Jacobian of \( \Phi \) at \( x \) in the sense of Clarke [11, Sect. 2.6].
COMPUTING THE NEAREST EUCLIDEAN DISTANCE MATRIX

\( e_i \) is the \( i \)th unit basis vector in \( \mathbb{R}^n \) and \( e \) is the vector of all ones. Define the Householder matrix \( Q \) by

\[
Q := I - \frac{2}{v^Tv}vv^T, \quad v = [1, \ldots, 1, \sqrt{n} + 1]^T \in \mathbb{R}^n,
\]

where \( v^T \) is the transpose of \( v \). We note that \( Q \) is symmetric and orthogonal: \( Q^2 = I \).

We often partition a matrix \( X \in S_n \) into blocks

\[
X = \begin{bmatrix} X_1 & x \end{bmatrix}^T x_0 \in \mathbb{R}^{n+1},
\]

\( X_1 \in S_{n-1}^n \), \( x \in \mathbb{R}^{n-1} \), \( x_0 \in \mathbb{R} \).

\( \Pi_{S^n_+}(X) \) is the orthogonal projection of \( X \) onto \( S^n_+ \). For a close convex cone \( C \) in \( S^n \), its polar cone \( C^* \) is defined by

\[
C^* := \{ X \in S^n : \langle X, A \rangle \leq 0 \ \forall \ A \in C \}.
\]

The normal cone \( N_{K^n_+}(A) \) of \( K^n_+ \) at \( A \in K^n_+ \) is defined by

\[
N_{K^n_+}(A) := \{ X \in S^n : \langle X, A - \overline{A} \rangle \leq 0 \ \forall \ A \in K^n_+ \}.
\]

Since \( K^n_+ \) is convex, the tangent cone \( T_{K^n_+}(A) \) of \( K^n_+ \) at \( A \in K^n_+ \) can be conveniently defined as the polar cone of \( N_{K^n_+}(A) \):

\[
T_{K^n_+}(A) := (N_{K^n_+}(A))^*.
\]

We let \( \text{lin}(T_{K^n_+}(A)) \) denote the largest linear space contained in \( T_{K^n_+}(A) \). \( A \circ B := [A_{ij}B_{ij}] \) is the Hadamard product between two matrices \( A \) and \( B \) of same size. For subsets \( \alpha, \beta \) of \( \{1, \ldots, n\} \), denote \( B_{\alpha\beta} \) as the submatrix of \( B \) indexed by \( \alpha \) and \( \beta \) (\( \alpha \) for rows and \( \beta \) for columns). \( B_{\alpha} \) denotes the submatrix consisting of columns of \( B \) indexed by \( \alpha \), and \( |\alpha| \) is the cardinality of \( \alpha \).

There are two known formulae for computing \( \Pi_{K^n_+} \). One is due to Hayden and Wells [25, Thm. 2.1]:

\[
A \in K^n_+ \iff QAQ = \begin{bmatrix} \hat{A} & \hat{a} \\ \hat{a}^T & \hat{a}_0 \end{bmatrix} \quad \text{and} \quad \hat{A} \in S^{n-1}_+, \text{ and } \hat{A} \in S^{n-1}_+,
\]

and

\[
\Pi_{K^n_+}(A) = Q \begin{bmatrix} \Pi_{S^{n-1}_+}(\hat{A}) & \hat{a} \\ \hat{a}^T & \hat{a}_0 \end{bmatrix} Q, \quad \forall \ A \in S^n,
\]

where and throughout this paper \( Q \) is the Householder matrix defined in (12). Because of (15), the cone \( K^n_+ \) can be described as follows:

\[
K^n_+ = \left\{ Q \begin{bmatrix} Z & z \\ z^T & z_0 \end{bmatrix} Q : \begin{array}{c} Z \in S^{n-1}_+ \quad z \in \mathbb{R}^{n-1} \quad z_0 \in \mathbb{R} \end{array} \right\}.
\]

Its polar cone \((K^n_+)^*\) is then given by

\[
(K^n_+)^* = \left\{ Q \begin{bmatrix} Z & 0 \\ 0 & 0 \end{bmatrix} Q : \begin{array}{c} Z \in -S^{n-1} \end{array} \right\}.
\]
The other projection formula is due to Gaffke and Mathar [17, Eq. 29]:

$$\Pi_{\mathcal{K}^n_r}(A) = A + \Pi_{\mathcal{S}^n_r}(-JAJ), \quad \forall A \in \mathcal{S}^n.$$  \hspace{1cm} (17)

We note that the original projection formula of Gaffke and Mathar is onto \((-\mathcal{K}^n_r)). Each formula has its own advantage. Formula (15) states that the projection is in fact carried out onto \(\mathcal{S}^n_{n-1}\), while (17) brings the formula to the defining space \(\mathcal{S}^n\). We will use Gaffke-Mathar formula in our numerical implementation and Hayden-Wells formula for our analysis because it brings out the rich structures that exist in \(T_{\mathcal{K}^n_r}(\overline{A})\).

### 2.2. Existence of Optimal Dual Solutions and Constraint Nondegeneracy

The following result on the coerciveness of the dual problem (8) ensures that it must have an optimal solution.

**Proposition 2.1.** The function \(\theta(\cdot)\) in (8) is coercive, i.e., \(\theta(y) \to +\infty\) as \(\|y\| \to +\infty\). Consequently, the dual problem (8) must have an optimal solution.

**Proof.** Suppose to the contrary that \(\theta(\cdot)\) is not coercive. Then there must exist a sequence \(\{y^k\}\) such that \(\|y^k\| \to +\infty\) and \(\theta(y^k) \leq c\) for some constant \(c > 0\). We consider the sequence \(\{y^k/\|y^k\|\}\), which, without loss of generality, is assumed to converge to \(y^*\). Because \(\mathcal{K}^n_r\) is a cone, we have

$$\frac{c}{\|y^k\|^2} \geq \frac{\theta(y^k)}{\|y^k\|^2} = \frac{1}{2} \left\| \Pi_{\mathcal{K}^n_r} \left( D/\|y^k\| + \text{Diag}(y^k)/\|y^k\| \right) \right\|^2 - \frac{1}{2} \|D\|^2/\|y^k\|^2.$$

Taking the limit on both sides of the above inequality, we have (due to the continuity of the projection operator \(\Pi_{\mathcal{K}^n_r}(\cdot)\))

$$\|\Pi_{\mathcal{K}^n_r}(\text{Diag}(y^*))\| \leq 0,$$

which means \(\Pi_{\mathcal{K}^n_r}(\text{Diag}(y^*)) = 0\). Consequently, \(\text{Diag}(y^*) \in (\mathcal{K}^n_r)^*\).

It follows from (16) that there exists \(Z \in -\mathcal{S}^n_{n-1}\) such that

$$\text{Diag}(y^*) = Q \begin{bmatrix} Z & 0 \\ 0 & 0 \end{bmatrix} Q \quad \text{or equivalently} \quad Q\text{Diag}(y^*)Q = \begin{bmatrix} Z & 0 \\ 0 & 0 \end{bmatrix}.$$

Obviously, the last column of \(Q\text{Diag}(y^*)Q\) is zero:

$$0 = Q\text{Diag}(y^*)Qe_n = -\frac{1}{\sqrt{n}}Q\text{Diag}(y^*)e = -\frac{1}{\sqrt{n}}Qy^*,$$

where we used \(Qe_n = -e/\sqrt{n}\). The nonsingularity of \(Q\) implies \(y^* = 0\), contradicting \(\|y^*\| = 1\). This proves that \(\theta(\cdot)\) is coercive.

Constraint nondegeneracy plays a very important role in optimization, see [3, Def. 5], [10, Def. 9], and [37, Sect. 2] for its use in SDP. Generally speaking, it ensures certain regularity of optimal solutions. For our problem (3), the constraint nondegeneracy is defined as follows.

**Definition 2.2.** We say that the constraint nondegeneracy holds at \(\overline{A} \in \mathcal{S}^n_r \cap \mathcal{K}^n_r\) if

$$\text{diag} \left( \text{lin} \left( T_{\mathcal{K}^n_r}(\overline{A}) \right) \right) = \mathbb{R}^n.$$  \hspace{1cm} (18)
Let \( \overline{A} \in K^n_+ \) and
\[
\overline{A} = Q \begin{bmatrix}
Z & z \\
\ast & z_0
\end{bmatrix} Q, \quad Z \in S^{n-1}.
\] (19)

Then \( Z \succeq 0 \) by (14). We assume that \( \text{rank}(Z) = r \) and let \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_r > 0 \) be the \( r \) positive eigenvalues of \( Z \) in nonincreasing order. Let \( \Lambda = \text{Diag}(\lambda_1, \ldots, \lambda_r) \). We assume that \( Z \) takes the following spectral decomposition
\[
Z = U \begin{bmatrix}
\Lambda & 0 \\
0 & 0
\end{bmatrix} U^T,
\] (20)
where \( U \in \mathbb{R}^{n \times (n-1)} \) and \( U^T U = I_{n-1} \). The normal cone \( \mathcal{N}_{K^n_+}(\overline{A}) \) is given by [19, Thm. 3.1].
\[
\mathcal{N}_{K^n_+}(\overline{A}) = \left\{ Q \begin{bmatrix}
U & 0 \\
0 & M
\end{bmatrix} U^T 0 \begin{bmatrix}
0 & 0 \\
0 & M
\end{bmatrix} U^T 0 Q : -M \in S^{n-r-1}_+ \right\}.
\]

Let
\[
\mathcal{U} := \begin{bmatrix}
U & 0 \\
0 & 1
\end{bmatrix} \in \mathbb{R}^{n \times n}.
\] (21)

Then \( \mathcal{U}^T \mathcal{U} = I \) and the normal cone can be equivalently written as
\[
\mathcal{N}_{K^n_+}(\overline{A}) = \left\{ Q \mathcal{U} \begin{bmatrix}
0 & 0 \\
0 & M
\end{bmatrix} 0 \begin{bmatrix}
0 & 0 \\
0 & M
\end{bmatrix} Q : -M \in S^{n-r-1}_+ \right\}.
\]

By the definition (13) of the tangent cone in terms of \( \mathcal{N}_{K^n_+}(\overline{A}) \), we have
\[
\mathcal{T}_{K^n_+}(\overline{A}) = \left\{ Q \mathcal{U} \begin{bmatrix}
\Sigma_1 & \Sigma_{12} \\
\Sigma_{12}^T & \Sigma_2
\end{bmatrix} a \begin{bmatrix}
a \\
a_0
\end{bmatrix} \mathcal{U}^T Q : \begin{array}{l}
\Sigma_1 \in S^r, \Sigma_2 \in S^{n-r-1}_+ \\
\Sigma_{12} \in \mathbb{R}^{r \times (n-r-1)} \\
a \in \mathbb{R}^{n-1}, a_0 \in \mathbb{R}
\end{array} \right\} \quad \text{(22)}
\]
\[
= \left\{ Q \begin{bmatrix}
U & 0 \\
0 & M
\end{bmatrix} U^T a \begin{bmatrix}
a \\
a_0
\end{bmatrix} Q : \begin{array}{l}
\Sigma_1 \in S^r, \Sigma_2 \in S^{n-r-1}_+ \\
\Sigma_{12} \in \mathbb{R}^{r \times (n-r-1)} \\
a \in \mathbb{R}^{n-1}, a_0 \in \mathbb{R}
\end{array} \right\}. \quad \text{(23)}
\]

The last equality used the facts that \( U \) is nonsingular and \([a^T, a_0]\) is not restricted.

Now we are ready to prove the following result.

**Theorem 2.3.** Constraint nondegeneracy holds at each feasible point \( \overline{A} \) of problem (3).

**Proof.** We only need to prove condition (18). It follows from (22) that
\[
\text{lin}(\mathcal{T}_{K^n_+}(\overline{A})) = \left\{ Q \mathcal{U} \begin{bmatrix}
\Sigma_1 & \Sigma_{12} \\
\Sigma_{12}^T & 0
\end{bmatrix} a \begin{bmatrix}
a \\
a_0
\end{bmatrix} \mathcal{U}^T Q : \begin{array}{l}
\Sigma_1 \in S^r \\
\Sigma_{12} \in \mathbb{R}^{r \times (n-r-1)} \\
a \in \mathbb{R}^{n-1}, a_0 \in \mathbb{R}
\end{array} \right\}. \quad \text{(24)}
\]

It is obvious from (23) that
\[
A = Q \begin{bmatrix}
0_{(n-1) \times (n-1)} & a \\
0 & a_0
\end{bmatrix} Q \in \text{lin}(\mathcal{T}_{K^n_+}(\overline{A})) \quad \forall [a^T, a_0] \in \mathbb{R}^n.
\]
Let \( b \in \mathbb{R}^n \) be arbitrary. We will find \( [a^T, a_0] \in \mathbb{R}^n \) such that

\[
\text{diag}(A) = b. \tag{25}
\]

We calculate the diagonal of \( A \). For \( i = 1, \ldots, n \), we have

\[
A_{ii} = e_i^T Q \begin{bmatrix}
0_{(n-1) \times (n-1)} & a \\
\frac{a}{a_0}
\end{bmatrix} = e_i^T \left( e_i^T Q \frac{2a}{a_0} \right) = \frac{1}{\sqrt{n}} e_i^T \left( e_i^T Q \right) \begin{bmatrix}
2a \\
a_0
\end{bmatrix}
\]

We therefore have

\[
\text{diag}(A) = -\frac{1}{\sqrt{n}} Q \begin{bmatrix}
2a \\
a_0
\end{bmatrix}.
\]

Substituting this into (25) to solve for \( a \) and \( a_0 \), we obtain

\[
\begin{bmatrix}
2a \\
a_0
\end{bmatrix} = -\sqrt{n} Q b.
\]

With such choice of \( a \) and \( a_0 \) in \( A \), we have \( b = \text{diag}(A) \in \text{diag} (\mathcal{J}_{K_+}(\overline{A})) \). This proves (18) and hence the constraint nondegeneracy at \( \overline{A} \).

Thm. 2.3 is not practical enough for our use. We now develop a result for later use. Let \( E_i := e_i e_i^T \) for \( i = 1, \ldots, n \) and

\[
B_i := Q E_i Q =: \begin{bmatrix}
B_i^1 & b^i \\
(b^i)^T & b_0^i
\end{bmatrix}
\]

with \( B_i^1 \in \mathcal{S}^{n-1} \).

Let \( U \) be defined as in (20). We define the corresponding index sets:

\[
\alpha(Z) := \{ i : \lambda_i > 0 \} \quad \text{and} \quad \overline{\alpha}(Z) := \{ 1, 2, \ldots, n-1 \} \setminus \alpha(Z). \tag{26}
\]

Whenever no confusion is caused, we abbreviate \( \alpha(Z), \overline{\alpha}(Z) \) as \( \alpha \) and \( \overline{\alpha} \) respectively.

We write

\[
U = [U_\alpha, U_{\overline{\alpha}}].
\]

We further define

\[
C_i := \begin{bmatrix}
U_\alpha^T B_i^1 U_\alpha & U_\alpha^T B_i^1 U_{\overline{\alpha}} \\
U_{\overline{\alpha}}^T B_i^1 U_\alpha & U_{\overline{\alpha}}^T B_i^1 U_{\overline{\alpha}}
\end{bmatrix}
\begin{bmatrix}
U^T b^i \\
(b^i)^T U
\end{bmatrix} - \begin{bmatrix}
0 & 0 \\
0 & U_{\overline{\alpha}}^T B_i^1 U_{\overline{\alpha}}
\end{bmatrix} 0 \tag{27}
\]

where \( U \) is defined by (21).

**Proposition 2.4.** The matrices \( \{C_i\}_{i=1}^n \) are linearly independent at each feasible point \( \overline{A} \) of (3).
Proof. We note that the constraint nondegeneracy condition (18) is equivalent to
\[ S^n_h + \text{lin}(\mathcal{T}_{K^*_n}(\overline{A})) = S^n, \]
which in turn is equivalent to
\[ \left( S^n_h \right)^\perp \cap \left( \text{lin}(\mathcal{T}_{K^*_n}(\overline{A})) \right)^\perp = \{ 0 \}, \quad (28) \]
where \((S^n_h)^\perp\) denotes the subspace orthogonal to \(S^n_h\).

Because of Thm. 2.3, (28) holds. We prove the claim by contradiction. Assume that \(\{ C_i \}_{i=1}^n\) are linearly dependent. Then there exists \(0 \neq h \in \mathbb{R}^n\) such that
\[ \sum_{i=1}^n h_i C_i = 0. \]
It follows from (27) that
\[ \sum_{i=1}^n h_i C_i = U^T \left( \sum (h_i B_i) \right) U - \begin{bmatrix} 0 & 0 \\ 0 & U^T \sum (h_i B_i^1) U_{\pi} \end{bmatrix} 0 \]
\[ = U^T \left( Q(\text{Diag}(h))Q \right) U - \begin{bmatrix} 0 & 0 \\ 0 & U^T \sum (h_i B_i^1) U_{\pi} \end{bmatrix} 0, \quad (29) \]
where we used the trivial identity
\[ \sum_{i=1}^n h_i B_i = Q(\text{Diag}(h))Q. \quad (30) \]
Hence, \(\sum_{i=1}^n h_i C_i = 0\) implies
\[ U^T \left( Q(\text{Diag}(h))Q \right) U = \begin{bmatrix} 0 & 0 \\ 0 & U^T \sum (h_i B_i^1) U_{\pi} \end{bmatrix} 0. \quad (31) \]
It is obvious that \(\text{Diag}(h) \in (S^n_h)^\perp\). For any \(A \in \text{lin}(\mathcal{T}_{K^*_n}(\overline{A}))\), we have
\[ \langle \text{Diag}(h), A \rangle = \langle U^T Q(\text{Diag}(h)) Q U, U^T Q A Q U \rangle = \langle U^T \sum (h_i B_i^1) U_{\pi}, 0 \rangle = 0. \]
The first equality used the fact that \(Q U\) is orthogonal because each of them is so. The second equality used (31) and the structure of \(\text{lin}(\mathcal{T}_{K^*_n}(\overline{A}))\) in (24). Hence
\[ \langle \text{Diag}(h), A \rangle = 0 \neq \text{Diag}(h) \in \left( S^n_h \right)^\perp \cap \left( \text{lin}(\mathcal{T}_{K^*_n}(\overline{A})) \right)^\perp, \]
which contradicts (28). This proves the linear independence of \(\{ C_i \}_{i=1}^n\). \qed

As a matter of fact, it is not hard to derive the constraint nondegeneracy at \(\overline{A}\) from the linear independence of \(\{ C_i \}_{i=1}^n\). In other words, linear independence of \(\{ C_i \}_{i=1}^n\) is equivalent to constraint nondegeneracy at \(\overline{A}\). It is interesting to note that this equivalent characterization is a natural extension of a result of Alizadeh, Haeberly, and Overton [3, Thm. 6] on primal nondegeneracy in SDP from \(S^n_h\) to \(K^*_n\).
3. Quadratic Convergence. This section is mainly concerned with the quadratic convergence of the Newton method (11). Globalizing the Newton method is straightforward as the dual problem (8) is convex (see Sect. 5). Our key result is that every matrix in $\partial^2 \theta(y)$ is positive definite when $y$ is an optimal solution of (8). This result will lead to the desired quadratic convergence. To facilitate our analysis, we need to study the structure of $\partial^2 \theta(y) = \partial F(y)$.

It follows from the definition of $F(y)$ in (9) and the Gaffke-Mathar formula (17) that (also using diag($D$) = 0)

$$F(y) = y + \text{diag}(\Pi_{S^2_+}(-J(D + \text{Diag}(y))J)).$$

The Jacobian chain rule of Clarke [11, Thm. 2.6.6] implies

$$\partial^2 \theta(y)h \subseteq h - \text{diag} \left( \partial \Pi_{S^2_+}(Y)(J(D(h))J) \right),$$

where $Y := -J(D + \text{Diag}(y))J$. We will reveal the rich structures in $\partial \Pi_{S^2_+}(Y)(J\text{Diag}(h)J)$ step by step so as to prove our ultimate result on quadratic convergence of (11).

3.1. Generalized Jacobian of $\Pi_{S^2_+}(\cdot)$. Let

$$Y := -J(D + \text{Diag}(y))J \quad \text{and} \quad Y = PA^T,$$

where $P^TP = I$ and $\Lambda := \text{Diag}(\lambda_1, \ldots, \lambda_n)$ with $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_n$ being eigenvalues of $Y$ in nonincreasing order. For those eigenvalues, define the corresponding symmetric matrix $\Omega \in S^n$ with entries

$$\Omega_{ij} := \max \{\lambda_i, 0\} + \max \{\lambda_j, 0\}, \quad i, j = 1, \ldots, n$$

where $0/0$ is defined to be 1.

We further define three index sets:

$$\alpha(Y) := \{i : \lambda_i > 0\}, \quad \beta(Y) := \{i : \lambda_i = 0\}, \quad \gamma(Y) := \{i : \lambda_i < 0\}.$$  

We will drop the dependence of those indices on $Y$ whenever no confusion is caused. We have the following formula of describing $\partial \Pi_{S^2_+}(Y)$.

**Proposition 3.1.** [43, Prop. 2.2] Suppose that $Y \in S^n$ has the spectral decomposition as in (33). Then $V \in \partial \Pi_{S^2_+}(Y)$ if and only if there exists $\tilde{V} \in \partial \Pi_{S^2_{+\beta}}(0)$ such that

$$V(H) = P \begin{bmatrix} \tilde{H}_{\alpha\alpha} & \tilde{H}_{\alpha\beta} & \Omega_{\alpha\gamma} \circ \tilde{H}_{\alpha\gamma} \\ \tilde{H}_{\alpha\beta}^T & \tilde{V} & 0 \\ \Omega_{\gamma\gamma} \circ \tilde{H}_{\alpha\gamma}^T & 0 & 0 \end{bmatrix} P^T, \quad \forall \ H \in S^n$$

where $\tilde{H} := P^THP$.

Therefore, to specify an element $V \in \partial \Pi_{S^2_+}(Y)$ one needs to specify the corresponding $\tilde{V}$ from $\partial \Pi_{S^2_{+\beta}}(0)$. It is usually complicated to specify all elements in $\partial \Pi_{S^2_{+\beta}}(0)$, see [32], which is solely devoted to a detailed characterization. But for us we only need the following property on $\tilde{V}$.

$$\langle Z_1, \tilde{V}(Z_2) \rangle \leq \|Z_1\| \|Z_2\|, \quad \forall \ Z_1, Z_2 \in S^{\beta}. $$
This can be easily proved by using [10, Eq. (17)]. The general description in (36) is not adequate for our further analysis. We need to break it into pieces that will reveal the structure of our problem. Next we establish a useful relationship between \( P \) and \( Q \).

### 3.2. Relationship between \( P \) and \( Q \)

The following identity has been used by Glunt et al. [19, P. 591].

\[
Q \begin{bmatrix} I_{n-1} & 0 \\ 0 & 0 \end{bmatrix} Q = J. \tag{38}
\]

It follows from (33) that

\[
Y = Q \begin{bmatrix} \hat{Y}_1 & 0 \\ 0 & 0 \end{bmatrix} Q, \tag{39}
\]

where we denote

\[
-\hat{Q}(D + \text{Diag}(y)) =: \begin{bmatrix} \hat{Y}_1 & \hat{y} \\ \hat{y}^T & 0 \end{bmatrix} \quad \text{with} \quad \hat{Y}_1 \in S^{n-1}. \tag{40}
\]

Let \( \hat{Y}_1 \in S^{n-1} \) take the spectral decomposition

\[
\hat{Y}_1 = W \hat{\Lambda} W^T, \tag{41}
\]

where \( \hat{\Lambda} := \text{Diag}(\hat{\lambda}_1, \ldots, \hat{\lambda}_{n-1}) \) with \( \hat{\lambda}_1 \geq \ldots \geq \hat{\lambda}_{n-1} \) being eigenvalues of \( \hat{Y}_1 \) and \( W \in \mathbb{R}^{(n-1)\times(n-1)} \), \( W^T W = I_{n-1} \). Define

\[
\hat{\alpha} := \{ i : \hat{\lambda}_i > 0 \}, \quad \hat{\beta} := \{ i : \hat{\lambda}_i = 0 \}, \quad \text{and} \quad \hat{\gamma} := \{ i : \hat{\lambda}_i < 0 \}, \tag{42}
\]

and

\[
W = [W_{\hat{\alpha}}, W_{\hat{\beta}}, W_{\hat{\gamma}}]. \tag{43}
\]

Then we have

\[
Y := \begin{bmatrix} \hat{Y}_1 & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} W & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{\Lambda} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} W^T & 0 \\ 0 & 1 \end{bmatrix}.
\]

This means that in addition to \( \{ \hat{\lambda}_1, \ldots, \hat{\lambda}_{n-1} \} \), 0 is the last eigenvalue of \( Y \) and \( e_{n} \) is the corresponding eigenvector. It follows from (39) that \( Y \) and \( Y \) share the same set of eigenvalues because \( Q \) is orthogonal. The relationship between index sets \( \alpha, \beta, \) and \( \gamma \) in (35) and \( \hat{\alpha}, \hat{\beta}, \) and \( \hat{\gamma} \) is

\[
\alpha = \hat{\alpha}, \quad \beta = \hat{\beta} \cup \{ |\hat{\alpha}| + |\hat{\beta}| + 1 \}, \quad \text{and} \quad \gamma = \{ i + 1 : i \in \hat{\gamma} \}.
\]

We define \( \bar{W} \) by

\[
\bar{W} := \begin{bmatrix} W_{\hat{\alpha}} & W_{\hat{\beta}} & 0 & W_{\hat{\gamma}} \\ 0 & 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} \bar{W}_{\alpha} & \bar{W}_{\beta} & \bar{W}_{\gamma} \end{bmatrix}, \tag{44}
\]

where

\[
\bar{W}_{\alpha} := \begin{bmatrix} W_{\hat{\alpha}} \\ 0 \end{bmatrix}, \quad \bar{W}_{\beta} := \begin{bmatrix} W_{\hat{\beta}} & 0 \\ 0 & 1 \end{bmatrix}, \quad \text{and} \quad \bar{W}_{\gamma} := \begin{bmatrix} W_{\hat{\gamma}} \\ 0 \end{bmatrix}.
\]

We then arrive at

\[
Y = Q\bar{Y}Q = Q\bar{W} \bar{\Lambda} \bar{W}^T Q.
\]

Therefore, the matrix \( P \) in (33) can be chosen to satisfy

\[
P = Q\bar{W} \quad \text{and} \quad \bar{W} \text{ is defined by (44)}. \tag{45}
\]
3.3. Structure of \( \partial \Pi_{S^n}(Y)(J \text{Diag}(h)J) \). We let

\[
H := J \text{Diag}(h)J \quad \text{and} \quad \tilde{H} := Q \text{Diag}(h)Q =: \begin{bmatrix} \frac{H_1}{h} & \frac{h}{h_0} \\
\end{bmatrix},
\]

where \( H_1 \in S^{n-1} \). By the identity in (38), we have

\[
H = Q \begin{bmatrix} H_1 \\
0 \\
\end{bmatrix} Q \quad \text{and hence} \quad QH = \begin{bmatrix} H_1 \\
0 \\
\end{bmatrix}.
\]

We also note from (45) that

\[
P_\alpha = QW_\alpha, \quad P_\beta = QW_\beta, \quad \text{and} \quad P_\gamma = QW_\gamma.
\]

We also recall from Prop. 3.1 that \( \tilde{H} = P_T HP \). It follows that

\[
\tilde{H}_{\alpha\alpha} = P_T^T H P_\alpha = W_\alpha^T Q H Q W_\alpha = W_\alpha^T H_1 W_\alpha,
\]

Similarly, we can calculate the following

\[
\tilde{H}_{\alpha\beta} = \begin{bmatrix} W_\alpha^T H_1 W_\beta \\
0 \\
\end{bmatrix}, \quad \tilde{H}_{\alpha\gamma} = W_\alpha^T H_1 W_\gamma,
\]

and

\[
\tilde{H}_{\beta\beta} = \begin{bmatrix} W_\beta^T H_1 W_\beta \\
0 \\
\end{bmatrix}, \quad \tilde{H}_{\beta\gamma} = W_\beta^T H_1 W_\gamma.
\]

We have now completed our preparation to describe any element in \( \partial \Pi_{S^n}(Y)(J \text{Diag}(h)J) \) for \( h \in \mathbb{R}^n \). The description only uses the spectral information of \( \tilde{Y}_1 \) in (41) and \( H_1 \) defined in (46). We note that \( h \) and \( h_0 \) in \( H \) of (46) do not appear in our description. We put it in a proposition.

**Proposition 3.2.** For any \( y \in \mathbb{R}^n \), let \( Y := -J(D + \text{Diag}(y))J \), which assumes the spectral decomposition (33). Let matrix \( \Omega \in S^n \) be defined in (34). Let \( H := J \text{Diag}(h)J \) for a given \( h \in \mathbb{R}^n \). Then a matrix \( L \in \partial \Pi_{S^n}(Y)(H) \) if and only if there exists \( \tilde{V} \in \partial \Pi_{S^n}(0) \) such that

\[
L = PW(H)P^T,
\]

where \( P \) is defined by (45) and

\[
W(H) := \begin{bmatrix}
W_\alpha^T H_1 W_\alpha & \frac{W_\alpha^T H_1 W_\beta}{0} & \Omega_{\alpha\gamma} \circ W_\alpha^T H_1 W_\gamma \\
\frac{W_\beta^T H_1 W_\alpha}{0} & \frac{W_\beta^T H_1 W_\beta}{0} & 0 \\
\Omega_{\alpha\gamma} \circ W_\gamma^T H_1 W_\gamma & 0 & 0
\end{bmatrix}.
\]

**Proof.** This result is just a new interpretation of the formula in Prop. 3.1 in terms of the above calculations. \( \Box \)

This proposition will be used to study the nonsingularity of \( \partial^2 \theta(y) \) in the next section. Let us first list two facts that will be used there.
The first fact is a simple observation on \( \|h\| \) for \( h \in \mathbb{R}^n \).

\[
\|h\|^2 = \|\text{Diag}(h)\|^2 = \|P^T \text{Diag}(h) P\|^2 = \|W^T Q \text{Diag}(h) Q W\|^2 = \|W^T H W\|^2. \tag{49}
\]

The second fact is about an inequality. Let

\[
G_\beta := \begin{bmatrix}
W^T H_1 W_\beta & W^T h \\
\hat{h}^T W_\beta & \hat{h}_0
\end{bmatrix}, \quad G_{\beta} := \begin{bmatrix}
W^T H_1 W_\beta & 0 \\
0 & 0
\end{bmatrix}.
\]

It is easy to see that \( \|G_\beta\| \leq \|G_{\beta}\| \) and

\[
\|G_\beta\|^2 - \|G_{\beta}\|^2 = 2\|W^T h\|^2 + \hat{h}_0^2.
\]

Hence we have

\[
\|G_\beta\|(\|G_\beta\| - \|G_{\beta}\|) \geq \|W^T h\|^2 + \frac{1}{2} \hat{h}_0^2. \tag{50}
\]

### 3.4. Nonsingularity of \( \partial^2 \theta(y) \)

We are ready to prove the following result.

**Theorem 3.3.** Let \( y \) be an optimal solution of the dual problem (8). Then every matrix \( M \in \partial^2 \theta(y) \) is positive definite.

*Proof.* We continue to use the notation developed so far. Let \( M \in \partial^2 \theta(y) \). Our purpose is to prove \( \langle h, M h \rangle > 0 \) for all \( 0 \neq h \in \mathbb{R}^n \). For such \( h \), we recall that \( H := J \text{Diag}(h) J \) and \( Y := -J(D + \text{Diag}(y)) J \). It follows from (32) and (47) that there exists \( \hat{V} \in \partial \Pi_{S_{\beta}}(Y) \) satisfying

\[
M h = h - \text{diag} \left( P W(H) P^T \right),
\]

where \( W(H) \) is defined by (48).

We now calculate \( \langle h, M h \rangle \).

\[
\langle h, M h \rangle = \|h\|^2 - \langle \text{Diag}(h), P W(H) P^T \rangle = \|h\|^2 - \langle P^T \text{Diag}(h) P, W(H) \rangle
\]

\[
= \|h\|^2 - \langle W^T Q \text{Diag}(h) Q W, W(H) \rangle \quad \text{(by (45))}
\]

\[
= \|W^T H W\|^2 - \langle W^T H W, W(H) \rangle \quad \text{(by (49), (46))}
\]

\[
= 2 \left\{ \|W^T h\|^2 + \|W^T H_1 W_\gamma\|^2 - \langle W^T H_1 W_\gamma, \Omega_{\alpha \gamma} \circ (W^T H_1 W_\gamma) \rangle \right\}
\]

\[
+ 2 \left\{ \|W^T h\|^2 + \|W^T H_1 W_\gamma\|^2 / 2 \right\}
\]

\[
+ \|G_\beta\|^2 - \langle G_\beta, \hat{V}(G_{\beta}) \rangle.
\]

The last equality made use of (48) and the structure of \( W^T H W \):

\[
W^T H W = \begin{bmatrix}
W^T h & W^T_\beta H_1 W_\gamma & W^T_\beta h & W^T_\beta H_1 W_\gamma \\
W^T_\beta H_1 W_\gamma & W^T_\beta h & W^T_\beta H_1 W_\gamma \\
\hat{h}^T W_\beta & \hat{h}^T W_\beta & \hat{h}_0 & \hat{h}_0 \\
W^T_\beta H_1 W_\gamma & W^T_\beta h & W^T_\beta H_1 W_\gamma
\end{bmatrix}.
\]
Define $\tau_{\text{max}} := \max_{i \in \alpha, j \in \gamma} \Omega_{ij}$. By (34), $0 < \tau_{\text{max}} < 1$. We continue to simplify $\langle h, Mh \rangle$.

\[
\langle h, Mh \rangle \geq 2 \left\{ \| W_\alpha^T h \|^2 + \| W_\beta^T h \|^2 + \| W_\gamma^T h \|^2 + (1 - \tau_{\text{max}}) \| W_\alpha^T H_1 W_\gamma \|^2 \right\} + \| W_\gamma^T H_1 W_\gamma \|^2 + (1 - \tau_{\text{max}}) \| W_\alpha^T H_1 W_\gamma \|^2
\]

\[
+ 2 \left\{ (1 - \tau_{\text{max}}) \| W_\alpha^T H_1 W_\gamma \|^2 + \| W_\beta^T H_1 W_\gamma \|^2 \right\} + \frac{1}{2} h_0^2
\]

\[
\geq 0. 
\]

(51)

Hence, the assumption $\langle h, Mh \rangle = 0$ would imply

\[
W_\alpha^T h = 0, \quad W_\beta^T h = 0, \quad W_\gamma^T h = 0, \quad \text{and} \quad h_0 = 0,
\]

(52)

and

\[
W_\alpha^T H_1 W_\gamma = 0, \quad W_\beta^T H_1 W_\gamma = 0, \quad W_\gamma^T H_1 W_\gamma = 0.
\]

(53)

Because of (43) and nonsingularity of $W$, (52) implies

\[
h = 0 \quad \text{and} \quad h_0 = 0.
\]

(54)

Since $y$ is an optimal solution of (8), $\overline{A} := \Pi_{\mathcal{K}_n^+} (D + \text{Diag}(y))$ is the optimal solution of (3) by (10). Obviously, $\overline{A}$ is feasible with respect to the constraints of (3). Constraint nondegeneracy holds at $\overline{A}$ due to Thm. 2.3. We assume $\overline{A}$ is decomposed as in (19). We now clarify what the matrix $Z$ is. We recall the decomposition (40) and Hayden-Wells formula (15) for $\Pi_{\mathcal{K}_n^+}$. It follows that

\[
\overline{A} = Q \begin{bmatrix} \Pi_{S_n^+}(-\hat{Y}_1) & -\hat{y} \\ -\hat{y}^T & -\hat{y}_0 \end{bmatrix} Q = Q \begin{bmatrix} \Pi_{S_n^+}(-\hat{\Lambda})W^T & -\hat{y} \\ -\hat{y}^T & -\hat{y}_0 \end{bmatrix} Q.
\]

Hence, the matrix $Z$ in (19) has the form

\[
Z = W\Pi_{S_n^+}(-\hat{\Lambda})W^T = W \begin{bmatrix} 0 & 0 \\ 0_{\hat{\gamma}} & -\hat{\Lambda}_{\hat{\gamma}} \end{bmatrix} W^T.
\]

(55)

Now we recall the definitions of $\alpha(Z)$ and $\bar{\alpha}(Z)$ in (26). The matrix $Z$ as decomposed in (20) also takes the following form.

\[
Z = U \begin{bmatrix} \Lambda_{\alpha} & 0 \\ 0 & 0 \end{bmatrix} U^T.
\]

We note that the indices in $\hat{\gamma}$ are

\[
\hat{\gamma} = \left\{ |\hat{\alpha}| + |\hat{\beta}|, |\hat{\alpha}| + |\hat{\beta}| + 1, \ldots, |\hat{\alpha}| + |\hat{\beta}| + |\hat{\gamma}| \right\} \quad \text{with} \quad |\hat{\alpha}| + |\hat{\beta}| + |\hat{\gamma}| = n - 1.
\]
By comparing (55) with (56), we have the following correspondence between eigenvalues indexed by \( \alpha \) and that by \( \hat{\gamma} \):
\[
|\alpha| = |\hat{\gamma}| \quad \text{and} \quad \lambda_i = -\hat{\lambda}_{n-i} \quad \text{for} \quad i \in \{1, 2, \ldots, |\alpha|\}.
\]

Let \( \hat{P} \) be the permutation matrix that maps the order sequence \( \{1, 2, \ldots, |\hat{\gamma}|\} \) to its reverse order sequence \( \{|\hat{\gamma}|, \ldots, 2, 1\} \). Then we have the following correspondence between eigenvectors in \( U \) and that in \( W \):
\[
U_{\alpha(i)} = W_{\hat{\gamma}i} \hat{P} \quad \text{and} \quad U_{\tau(z)} = W_{\tau} \quad \text{with} \quad \tau := \hat{\alpha} \cup \hat{\beta}.
\]

Then the matrices \( \{C_i\}_{i=1}^{\infty} \) defined in (27) are linearly independent by Prop. 2.4. It follows from (46), (54), and (30) that
\[
H = Q \text{Diag}(h) Q = \begin{bmatrix}
H_\alpha & h_0 \\
\theta & h_0
\end{bmatrix} = \begin{bmatrix}
H_1 & 0 \\
0 & 0
\end{bmatrix} \quad \text{and} \quad \sum_{i=1}^{n} h_i B_i^1 = H_1.
\]

We recall that \( \bar{U} \) is defined in (21). Now we consider the linear combination \( \sum_{i=1}^{n} h_i C_i \), which has been derived in (29):
\[
\sum_{i=1}^{n} h_i C_i = \bar{U}^T (Q \text{Diag}(h) Q) \bar{U} - \begin{bmatrix}
0 & U_{\tau}^T \sum (h_i B_i^1) U_{\tau} \\
0 & 0
\end{bmatrix} = \begin{bmatrix}
U_i^T H_1 U_\alpha & U_i^T H_1 U_{\tau} \\
0 & 0
\end{bmatrix} = \begin{bmatrix}
\bar{P}^T W_{\hat{\gamma}} W_{\tau} H_1 \bar{P} & \bar{P}^T W_{\hat{\gamma}} H_1 W_{\tau} \\
W_{\tau}^T H_1 W_{\tau} & 0
\end{bmatrix}.
\]

Consequently, (53) forces \( \sum_{i=1}^{n} h_i C_i = 0 \). The linear independence of \( \{C_i\} \) in turn forces \( h = 0 \). Therefore, \( (h, Mh) = 0 \) if and only if \( h = 0 \). In other words, \( (h, Mh) > 0 \) for \( 0 \neq h \in \mathbb{R}^{n} \) by (51). This proves that \( M \) is positive definite.

We now state a couple of consequences of Thm. 3.3. The first is on the uniqueness of the optimal solution of the dual problem (8). Let us regard the gradient function \( F(y) = \nabla \theta(y) \) as a mapping from \( \mathbb{R}^{n} \) to \( \mathbb{R}^{n} \). The generalized Jacobian \( \partial F(y) \) is said to be of maximal rank provided that every matrix \( M \) in \( \partial F(y) \) is of maximal rank (i.e., nonsingular) [11, P. 253]. It follows from Thm. 3.3 that \( \partial F(y^*) \) is of maximal rank provided that \( y^* \) is an optimal solution of (8). Then, the inverse function theorem of Clarke [11, Thm. 7.1.1] and the convexity of (8) lead to the following result.

Corollary 3.4. The dual problem (8) has a unique optimal solution.

The second consequence of Thm. 3.3 is about the quadratic convergence of the Newton method (11). We state it as a theorem.

Theorem 3.5. The Newton method (11) is quadratically convergent provided that \( y^0 \) is sufficiently close to the unique optimal solution \( y^* \) of (8).

Proof. In the quadratic convergence-rate theorem of Qi and Sun [40, Thm. 3.2] for general semismooth Newton methods, there are three conditions: (i) The function \( F \) is strongly semismooth, which is true for our case because it is a composition of linear mappings and the strongly semismooth mapping \( \Pi_{S^2}(\cdot) \) [44]. (ii) Every matrix in the generalized Jacobian of \( \partial F(y^*) \) is nonsingular, which has been proved in Thm. 3.3. The last condition is that the initial point \( y^0 \) stays close to \( y^* \). This proves our result.

Since (8) is convex, globalization of the Newton method (11) is an easy task. We simply use one of the well developed globalization method studied by Qi and Sun [38] in our numerical experiment.
4. Application to the H-weighted Problem. As briefly mentioned in Introduction, the \( H \)-weighted problem (4) is much more difficult to solve than the unweighted case (3). In this section, we develop a global method for this difficult problem. The most important feature of this method is that each subproblem is a diagonally weighted problem of (3), and this subproblem can be efficiently solved by a Newton method similar to (11). The bridge that links the \( H \)-weighted problem and the diagonally weighted problem is the majorization approach introduced by Gao and Sun [18] for the \( H \)-weighted nearest correlation matrix problem. We refer to [18] for more information about the majorization approach initially used in multidimensional scaling. We will first demonstrate how this approach works for (4).

4.1. The Majorization Approach. Denote the objective function in (4) by
\[
 f(X) = 0.5\|H \circ (X - D)\|^2.
\]
Obviously, \( f(\cdot) \) is quadratic and its Taylor expansion at a given point \( Y^k \in S^n \) is
\[
 f(X) = f(Y^k) + \langle H \circ H \circ (Y^k - D), X - Y^k \rangle + 0.5\|H \circ (X - Y^k)\|^2.
\]
We replace the quadratic term by a simpler function \( \|W^{1/2}(X - Y^k)W^{1/2}\|^2 \), which satisfies
\[
 \|W^{1/2}(X - Y^k)W^{1/2}\|^2 \geq \|H \circ (X - Y^k)\|^2, \quad \forall X \in S^n
\]
where \( W := \text{Diag}(w) \) and \( 0 < w \in \mathbb{R}^n \). A particular choice recommended by Gao and Sun [18] is
\[
 w_i := \max\{\tau, \max\{H_{ij} : j = 1, \ldots, n\}\}, \quad i = 1, \ldots, n, \tag{57}
\]
where \( \tau > 0 \) is a constant. Define
\[
 f_k(X) := f(Y^k) + \langle H \circ H \circ (Y^k - D), X - Y^k \rangle + 0.5\|W^{1/2}(X - Y^k)W^{1/2}\|^2. \tag{58}
\]
We certainly have the following property
\[
 f_k(X) \geq f(X) \quad \forall X \in S^n \quad \text{and} \quad f_k(Y^k) = f(Y^k). \tag{59}
\]
Because of this property, \( f_k(X) \) is called a majorization of \( f \) at \( Y^k \). The majorization approach aims to solve the following problem:
\[
 \min_{X} f_k(X), \quad \text{s.t.} \quad X \in S^n_k \cap K^n_+ \tag{60}
\]
We note that problem (60) is strictly convex, it has a unique solution, denoted by \( X^{k+1} \). We then have (because of (59))
\[
 f(X^{k+1}) \leq f_k(X^{k+1}) \leq f_k(Y^k) = f(Y^k). \tag{61}
\]
In other words, the solution of (60) provides a better point \( X^{k+1} \) than \( Y^k \) in terms of the original objective function. When \( Y^k \) is chosen to be \( X^k \), property (61) is known as the sandwich property and the majorization approach would produce a sequence \( \{X^k\} \) satisfying \( f(X^{k+1}) \leq f(X^k) \).

Numerical implication of the majorization approach is then to solve a sequence of the problem (60) starting from \( X^0 \). Theoretically, we get a sequence of \( \{X^k\} \) with decreasing function values if we choose \( Y^k = X^k \). As a matter of fact, there are other (better) choices for \( Y^k \). We will describe one in Subsect. 4.3. Numerically, this approach is sensible only if the new problem (60) is much easier to solve than the original problem. We demonstrate below it is the case.
4.2. Solving Subproblem (60). It is observed that problem (60) is actually a diagonally weighted problem of (3). To see this, we note that

\[ f_k(X) = \frac{1}{2} \| W^{1/2} (X - (Y^k - D^k)) W^{1/2} \|^2 + f(Y^k) - \frac{1}{2} \| W^{-1/2} (H \circ H \circ (Y^k - D)) W^{-1/2} \|^2, \]

where \( D^k := W^{-1}(H \circ H \circ (Y^k - D)) W^{-1}. \) Ignoring the constant term in \( f_k, \) problem (60) is equivalent to

\[ \min \frac{1}{2} \| W^{1/2} (X - \overline{D}^k) W^{1/2} \|^2, \quad \text{s.t.} \quad X \in S^n_h \cap K^n_+, \tag{62} \]

where \( \overline{D}^k := Y^k - D^k. \) Because of \( W = \text{Diag}(w), \) we call this problem diagonally weighted version of problem (3).

Let \( \tilde{X} := W^{1/2} X W^{1/2} \) and \( \tilde{D}^k := W^{1/2} \overline{D}^k W^{1/2}. \)

Then problem (62) is equivalent to

\[ \min \frac{1}{2} \| \tilde{X} - \tilde{D}^k \|^2 \quad \text{s.t.} \quad W^{-1/2} \tilde{X} W^{-1/2} \in S^n_h \cap K^n_+. \tag{63} \]

It is easy to verify that (because \( W \) is diagonal)

\[ W^{-1/2} \tilde{X} W^{-1/2} \in S^n_h \quad \text{if and only if} \quad \tilde{X} \in S^n_h, \]

and

\[ W^{-1/2} \tilde{X} W^{-1/2} \succeq 0 \quad \text{on} \quad \{ e \}^\perp \quad \text{if and only if} \quad \tilde{X} \succeq 0 \quad \text{on} \quad \left\{ W^{1/2} e \right\}^\perp. \]

Define the closed convex cone

\[ K^n_w := \left\{ X \in S^n : X \succeq 0 \quad \text{on} \quad \left\{ W^{1/2} e \right\}^\perp \right\}. \]

It follows from (63) that (62) is equivalent to

\[ \min \frac{1}{2} \| \tilde{X} - \tilde{D}^k \|^2 \quad \text{s.t.} \quad \tilde{X} \in S^n_h \cap K^n_w. \tag{64} \]

This problem is almost the same as (3) except that \( K^n_+ \) is being replaced by \( K^n_w. \) We can develop Newton method for this problem just as we have done for problem (3). We summarize this procedure below.

The corresponding dual problem and its first-order optimality condition are (see (8) and (9) respectively for problem (3)):

\[ \min_{y \in \mathbb{R}^n} \theta_w(y) := \frac{1}{2} \| \Pi_{K^n_w} (\overline{D}^k + \text{Diag}(y)) \|^2 - \frac{1}{2} \| \overline{D}^k \|^2; \tag{65} \]

and

\[ F_w(y) := \nabla \theta_w(y) = \text{diag} \left( \Pi_{K^n_w} (\overline{D}^k + \text{Diag}(y)) \right) = 0. \]
The Newton method therefore takes the following form (see (11)):
\[ y^{j+1} = y^j - V^{-1}_j F_w(y^j), \quad j = 0, 1, 2, \ldots \]  
(66)
where \( V_j \in \partial F_w(y^j) \).

In order to implement the Newton method (66), we need to characterize the projection \( \Pi_{K_n^+} (A) \) for any \( A \in S^n \). This can be done as follows. Let \( Q \) be the Householder transformation that maps the vector \( W^{1/2}e \) to \([0, \ldots, 0, -\|W^{1/2}e\|]^T\). Let
\[ v := \begin{bmatrix} \sqrt{w_1}, \ldots, \sqrt{w_{n-1}}, \sqrt{w_n} + \sqrt{\sum_{i=1}^{n} w_i} \end{bmatrix}^T. \]

Then
\[ Q = I - \frac{2}{v^Tv} vv^T. \]

According to [25, Thm. 2.1] (take \( S = W^{1/2}e \) there), we have
\[ \Pi_{K_n^+} (A) = Q \begin{bmatrix} \Pi_{S^{n-1}}(-\hat{A}_1) & \hat{a} & \hat{a}_0 \end{bmatrix} Q, \quad \forall \ A \in S^n \]
where
\[ QAQ =: \begin{bmatrix} \hat{A}_1 & \hat{a} & \hat{a}_0 \end{bmatrix}, \quad \text{with} \ \hat{A}_1 \in S^{n-1}, \ \hat{a} \in \mathbb{R}^{n-1}, \ \hat{a}_0 \in \mathbb{R}. \]

Let
\[ J := Q \begin{bmatrix} I_{n-1} & 0 \\ 0 & 0 \end{bmatrix} Q = I - \frac{1}{\sqrt{w}} \sqrt{w} \sqrt{w}^T \quad \text{with} \ \sqrt{w} := \begin{bmatrix} \sqrt{w_1} \\ \vdots \\ \sqrt{w_n} \end{bmatrix}. \]

Then the corresponding formula (17) of Gaffke and Mathar is
\[ \Pi_{K_n^+} (A) = A + \Pi_{S^n^+} (-JAJ). \]

We can repeat the analysis conducted in Subsect. 2.2 and Sect. 3 to conclude that the Newton method (66) is quadratically convergent (see Thm. 3.5). We omit the details.

### 4.3. Global Method for the \( H \)-weighted Problem.
Having addressed the quadratic convergence of the Newton method (66), we are ready to formally state our global method for the \( H \)-weighted problem (4). There exist a couple of globalization strategies. One is to follow the algorithmic framework of Gao and Sun [18] based on the majorization argument (e.g., choose \( Y_k = X_k \)). Another is to cast the majorization function \( f_k \) as a proximal gradient approximation to the objective function \( f \) and hence the resulting proximal gradient method can be applied. Our numerical results (not reported here) suggest that the second strategy works better. In this paper, we adopt the Accelerated Proximal Gradient (APG) method (e.g., choose \( Y_k \) to be an extrapolation of the two iterates \( X_k \) and \( X_{k-1} \)), recently studied by Jiang et al. [29] for large scale linearly constrained convex QSDP. We describe this method below.

**Algorithm 4.1.** (Inexact Accelerated Proximal Gradient Method: IAPG)
Step 1. Choose $X^0 \in S^n$. Let $Y^0 := X^0$, $t_0 := 1$. Set $k := 0$.

Step 2. Define the function $f_k$ by (58). Find an approximate minimizer $X^{k+1}$ of the problem (60).

Step 3. Compute $t_{k+1} := \left(1 + \sqrt{1 + 4t_k^2}\right)/2$.

Step 4. Compute

$$Y^{k+1} := X^{k+1} + \left(t_k - \frac{1}{t_{k+1}}\right) (X^{k+1} - X^k).$$

Let $k := k + 1$ and return to Step 2.

We have the following remarks regarding this algorithm.

(R1) An obvious choice of the initial point $X^0$ is obtained by solving the unweighted problem (3). If we keep $t_k = 1$ instead of updating $t_k$ in Step 3, Alg. 4.1 becomes the majorization method of Gao and Sun [18].

(R2) The subproblem (60) is solved by the Newton method (66). Let $y^{k+1}$ be the approximate solution obtained by this Newton method. Then $X^{k+1}$ is given by

$$X^{k+1} := W^{-1/2} \bar{X}^{k+1} W^{-1/2} \quad \text{and} \quad \bar{X}^{k+1} := \Pi_{K_n^w}(\bar{D}^k + \text{Diag}(y^{k+1})).$$

We also calculate

$$Z^{k+1} := W^{1/2}(\bar{X}^{k+1} - (\bar{D}^k + \text{Diag}(y^{k+1}))) W^{1/2}.$$ 

If $y^{k+1}$ is the exact solution of the dual problem (65), then $X^{k+1}$ is the optimal solution of (62) and $(Wy^{k+1}, Z^{k+1})$ are the Lagrange multipliers corresponding to the two constraints in (62). Consequently, $\nabla f_k(X^{k+1}) - \text{Diag}(Wy^{k+1}) - Z^{k+1} = 0$. Since the dual problem (65) is solved approximately, $X^{k+1}$ is only an approximate solution of (62) and $(Wy^{k+1}, Z^{k+1})$ are approximate multipliers. This is why the method is called the inexact APG (see [29] for more detailed justification why only solving the subproblem to certain accuracy is still adequate to obtain the desired complexity result described in (R4)).

(R3) The level of the accuracy for each subproblem can be specified, but with involved formulations. Interested reader can refer to [29, Eq. (32)] for those formulations. We simply use the stopping criterion, proposed by [29], to terminate the Newton method (66) for the dual problem (65) when

$$\|\nabla \theta_w(y^{k+1})\| \leq \min \left\{ \frac{1}{t_k^{3.1}}, \ 0.2\|\nabla f_k(X^k) - \text{Diag}(Wy^k) - Z^k\| \right\}.$$ 

Because $t_k$ increases to $\infty$, the approximate solution $y^{k+1}$ (and hence $X^{k+1}$) becomes more and more accurate as the algorithm progresses.

(R4) It has become well known (because of the work [35, 4, 46] and many others) that APGs possess the following complexity result:

$$f(X^k) - f(X^*) = O(1/k^2),$$

where $X^*$ is an optimal solution of (4). For the inexact APG described in Alg. 4.1, the above complexity still holds (see [29, Thm. 3.1]) subject to the subproblem being solved to certain accuracy. We omit the details. Our main contribution in applying IAPG is that the subproblem (60) can be efficiently solved by applying the Newton method (66) to its dual problem (65).

(R5) Without a proper convergence check, Alg. 4.1 may lead to an infinite loop. In our implementation, we used the stopping criterion (69) to terminate Alg. 4.1.
5. Numerical Results. In this section, we conduct numerical tests on both problem (3) and the $H$-weighted problem (4). For the former, we use the Newton method (11) and for the latter we use Alg. 4.1. At each of its iterations, Alg. 4.1 uses the Newton method (66) to solve its subproblem (62). Since both Newton methods in their current forms are only locally quadratically convergent, we used a globalized version of each of the Newton methods in our implementation. The globalized version we used is taken from [38, Alg. 5.1]. This globalized Newton method is globally and quadratically convergent (see the convergence analysis in [38, Sect. 5]).

We just like to make three remarks about this globalized Newton method. We use (11) as an example. The first remark is about calculating the matrix $V_{y}$. This can be done by adapting the computing procedure of [38, Sect. 5 (a)] to our function $F$. We summarize the calculation in a lemma. For simplicity, we drop the iteration index $k$ on $y$. We also recall that $E$ is the matrix of all ones.

**Lemma 5.1.** (Computing $V_{y} \in \partial F(y)$) Let $Y := -J(D + \text{Diag}(y))J$ have the spectral decomposition (33), with index sets $\alpha, \beta, \gamma$ being defined by (35). Then a matrix $V_{y} \in \partial F(y)$ can be computed as follows.

\[
V_{y}h = h - \text{diag}(P(M_{y} \circ (P^{T}H)P^{T}))P^{T} \quad \forall h \in \mathbb{R}^{n},
\]

where $H := J\text{Diag}(h)J$ and $M_{y}$ is defined by

\[
M_{y} := \begin{pmatrix}
E_{\alpha\alpha} & E_{\alpha\beta} & (\tau_{ij}(y))_{i \in \alpha, j \in \gamma} \\
E_{\beta\alpha} & 0 & 0 \\
(\tau_{ij}(y))_{i \in \alpha, j \in \gamma} & 0 & 0
\end{pmatrix}, \quad \tau_{ij}(y) := \frac{\lambda_{i} - \lambda_{j}}{\lambda_{i}}, \quad i \in \alpha, j \in \gamma.
\]

Evaluating the explicit form of $V_{y}$ costs a prohibitive $O(n^{4})$ operations. We therefore choose the conjugate-gradient (CG) method, which requires matrix-vector products only and avoids computing the explicit form of $V_{y}$, to solve the Newton equation (11). The second remark is about preconditioning CG by the diagonal preconditioner of $V_{y}$. The preconditioner can be calculated by adapting the computing procedure of [7, Sect. 3.2] for the problem (7) to our case. The computational complexity is about $2n^{3}$, similar to that of [7].

Our last remark is about extending the Newton method to handle additional fixed distance constraints:

\[X_{ij} = D_{ij} \quad \text{for} \quad (i, j) \in \mathcal{B},\]

where $\mathcal{B}$ is the index set that fixes those known distances $D_{ij}$. Toh [45] included such constraints in solving (5). Test example 5.6 considers such additional constraints. Our methodology and computation can be extended to this case in a natural way. To see this, let $\mathcal{A}^{\circ} : \mathcal{S}^{n} \mapsto \mathbb{R}^{\mathcal{B}}$ denote the linear mapping that fixes the off-diagonal distances in (67) indexed by $\mathcal{B}$. We further let

\[b := (D_{ij})_{(i,j) \in \mathcal{B}} \in \mathbb{R}^{\mathcal{B}} \quad \text{and} \quad \mathcal{A}(X) := \begin{pmatrix}
\text{diag}(X) \\
\mathcal{A}^{\circ}(X)
\end{pmatrix}.
\]

For two column vectors $y$ and $z$, we use Matlab notation $(y; z)$ to denote the column vector $(y^{T}, z^{T})^{T}$. The nearest EDM problem (see (3)) that has the extra constraints (67) becomes

\[
\min \|D - X\|^{2}/2 \quad \text{s.t.} \quad \mathcal{A}(X) = (0; b) \quad \text{and} \quad X \in \mathcal{K}_{n}^{+}.
\]
The corresponding dual problem becomes (see (8))
\[
\min_{(y,z)\in\mathbb{R}^{n+|E|}} \theta(y, z) := \|\Pi_{K_+} (D + A^*(y; z))\|^2/2 - \langle b, z \rangle - \|D\|^2/2,
\]
with \(A^*\) being the adjoint of \(A\). The first-order optimality condition becomes (see (9))
\[
F(y; z) := \nabla \theta(y; z) = A \left( \Pi_{K_+} (D + A^*(y; z)) \right) - (0; b) = (0; 0).
\]
The Newton method becomes (see (11))
\[
(y^{k+1}; z^{k+1}) = (y^k; z^k) - V_k^{-1} F(y^k; z^k), \quad k = 1, 2, \ldots
\]
where \(V_k \in \partial F(y^k; z^k)\). The new dual problem as well as the function \(F(y; z)\) are structurally similar to what we have in (8) and (9). As a consequence, the calculation of the generalized Jacobian matrix \(V_k\), which is essential to our Newton method, can be done via Lemma 5.1 with \(\text{diag}\) being replaced by \(A\) and \(\text{Diag}\) by \(A^*\). Moreover, the preconditioning CG used to solve the Newton equation goes through without any difficulties. However, if we have too many extra constraints of the type (67), we may lose the property of constraint nondegeneracy, which in turn may destroy the quadratic convergence of the Newton method. We like to point out that it is a very complicated issue to know what constraints enjoy the constraint nondegeneracy and what do not.

We will test the following problems. The first two problems are of dense type, i.e., \(D_{ij} \neq 0\) when \(i \neq j\), while the remaining three enjoy certain sparsity patterns. The first three problems are the type of unweighted problem (3) and the last two are of \(H\)-weighted problem (4). Examples 5.3 - 5.6 refer to the EDM1 problem of Toh [45].

**Example 5.2.** [19] The predistance matrix \(D\) is randomly generated with values uniformly distributed between \(10^{-5}\) and 10.

**Example 5.3.** This problem is a slight modification of EDM1 problem of Toh [45]. First, we generate \(n\) random points, \(x_1, \ldots, x_n\), in the unit cube centered at the origin in \(\mathbb{R}^3\). We calculate \(D_{ij} = \|x_i - x_j\|^2\) (the squared distance between \(x_i\) and \(x_j\)). We then add to \(D\) an \(n \times n\) random symmetric matrix with entries in \([-\alpha, \alpha]\), where \(\alpha = 0.3\) in our test.

**Example 5.4.** This is EDM1 problem of [45] except that the \(H\)-weight matrix is taken to be \(H = E\). First, we generate \(n\) random points, \(x_1, \ldots, x_n\), in the unit cube centered at the origin in \(\mathbb{R}^3\). Then we set \(D_{ij} = \|x_i - x_j\|^2\) if the distance is less than a certain cut-off distance \(R\); otherwise, set \(D_{ij} = 0\). \(R = 1\) in our test.

**Example 5.5.** This is EDM1 problem of [45] except that we do not have fixed distances. Generate matrix \(D\) as in Example 5.4 with various choices of \(R\). The weight matrix \(H\) is chosen to be the 0-1 matrix having the same sparsity pattern as \(D\). Density is calculated by \(\text{nnz}(D)/\text{numel}(D)\).

**Example 5.6.** This is EDM1 problem of [45]. Generate \(D\) and \(H\) as in Example 5.5. The set of indices where additional distances of the type (67) are fixed is given by \(B := \{(i, j): D_{ij} \neq 0, j = 1, \ldots, n\}\).

All tests were carried out using the 64-bit version of MATLAB R2011b on a Windows 7 desktop with 64-bit operating system having Intel(R) Core(TM) 2 Duo CPU of 3.16GHz, and 4.0 GB of RAM. In Table 1, we compare the Newton method with \textsc{map} [19] and the \textsc{qsdp} solver of Toh [45]. It follows from [17] or [31, Thm. 5.1]
that the alternating projection method is actually the gradient method for the dual problem with step size 1. Therefore, the error measured between successive iterates by MAP is the norm of the gradient $\|\nabla \theta(y)\|$. Therefore, we terminate MAP when

$$\text{Res} := \|\nabla \theta(y^k)\| \leq \text{tol},$$

(68)

with $\text{tol} = 10^{-5}$, and we stop the Newton method when (68) is satisfied with $\text{tol} = 10^{-6}$. The reason why we chose $10^{-5}$ for MAP is that it run into difficulties in some cases for higher accuracy (e.g., took too many iterations to have one more digit accuracy). On the contrary, the Newton method can quickly reach a higher accuracy. This is well reflected by the cpu time (in hh:mm:ss format) and the number of iterations (Iter columns) used by the two methods. The starting point for both methods was set to be 0 and the maximum iterations of MAP is capped at 2000. As for the QSDP solver, we used the default parameter settings. The Obj column contains returned objective function values by each method. The results reported below are the average on 10 randomly generated instances of each test problem.

The performance of the Newton method on unweighted problems in Table 1 is outstanding. It took under 1 minute to solve problems with $n = 2000$, which is equivalent to about 2 million independent variables in each problem. An interesting observation is that once it reached the level $\|\nabla \theta(y^k)\| \leq 10^{-1}$, the Newton method converges at a quadratic rate, taking just a few more steps to reach the required accuracy of $10^{-6}$. This observation seems independent of problem size and probably justifies why it took only about 4-8 steps to terminate for all the problems. On the contrary, MAP used an increasing number of iterations as $n$ increases. We note that the complexity of one iteration of MAP is about one full eigenvalue-eigenvector decomposition. The large number of iterations needed by MAP slows its convergence and took long time to terminate. For example, Newton took about 8 seconds to solve Example 5.4 ($n = 1000$) while MAP used about 13 minutes. When $n = 2000$, the numbers are 51 seconds for Newton vs nearly 2 hours for MAP, which reached the maximum iteration with $\|\theta(y^k)\| \approx 10^{-3}$. This less accuracy of the final iterate is reflected by the corresponding (slightly) lower objective function value 84996 than 84998 returned by the Newton method. This is because the final matrix returned by MAP is not yet (but close to) a EDM due to the low accuracy. QSDP suffers similar difficulties as MAP when $n$ gets bigger than 1000. When $n = 2000$, QSDP took more than 9 hours to terminate. Being a general solver for quadratic SDPs, we feel that QSDP has much room to improve on our test problems by taking advantage of the problem structure. An encouraging observation is that all methods were able to return almost the same objective function value on each test problem.

One important issue that was brought up by the referee is the scaling when using the Newton method. The following test problem was suggested by the referee. First, the $n$ points $X = [x_1, x_2, \ldots, x_n]$ are generated by $X = \text{rand}(n-1,n)$. We then calculate $D_{ij} = \|x_i - x_j\|^2$. Finally, $D$ is perturbed by small quantities via $D = D + 0.01 \times \text{randn}(n,n)$. For example, when $n = 800$, the Newton method, without scaling, would lose its quadratic convergence. This is because the step length was too small after a couple of iterations. The culprit is that $D$ contains large distances. When $D$ is scaled to $D/\max(D_{ij})$ to bring all distances between 0 and 1, the quadratic convergence returns for this scaled matrix. Of course, the obtained solution should be scaled back by multiplying $\max(D_{ij})$. For this particular problem ($n = 800$), we have Iter = 1; cpu = 0.7s; Res = 1.43E-5; and Obj = 2.12E-3. The corresponding result for MAP (no scaling was used) are Iter = 2; cpu = 0.8s; Res = 4.53E-7; and Obj
= 2.12E-3. For other values of \( n \), we obtained similar results (e.g., Iter =1 for the Newton method and 2 for MAP). The reason why Newton and MAP took just one or two iterations is that the starting point is very close to the true solution, bearing in mind that the true distance matrix is only perturbed by a small amount. For a general discussion on the need of scaling in optimization methods, we refer to [5, Sect. 1.10, Scaling].

In Tables 2 and 3, we report our numerical experience with Alg. 4.1 and QSDP solver on \( H \)-weighted problems with (e.g., Example 5.6) and without (e.g., Example 5.5) additional fixed distances (MAP is not applicable to this kind of problems). In our implementation, we used \( \tau = 0.1 \) (see (57)). We terminate Alg. 4.1 when

\[
\text{fprog} := \frac{|\sqrt{f(X_{k-1})} - \sqrt{f(X_k)}|}{\max\{100, \sqrt{f(X_{k-1})}\}} \leq 10^{-5}.
\] (69)

In other words, whenever there is lack of the relative progress on the successive objective function values we stop the algorithm. This stopping criterion was suggested by Gao and Sun [18] for their majorization method. We once again used the default parameter values for QSDP. In particular, it was terminated when the relative gap defined in [45] is less than \( 10^{-5} \).

It is observed that the \( H \)-weighted problem is much more difficult to solve than the unweighted one. The difficulty level seems to increase as the density of \( H \) decreases. In Table 2, we tested Examples 5.5 and 5.6 with fixed dimension \( n = 500 \), but with varying densities (ranging from 99.79% to 2.63%). In Table 3, we tested the two examples with varying dimensions (from \( n = 100 \) to 2000) and varying densities (from 91.98% to 2.59%). It is evident that our algorithm performed significantly faster than QSDP for all the problems. An important observation from those tables as well as from our extensive numerical experiments unreported here is that when the density is above about 10%, both Alg. 4.1 and QSDP solver return almost the same objective function value. However, when it is below the 10%, QSDP often terminated early as the psqmr solver used in QSDP reached the default maximum number of steps. This observation can be clearly seen from Table 3 for \( n \geq 500 \) with density less than 5%. It is also worth to mention that one can stop Alg. 4.1 at any iteration once a satisfactory approximate solution is obtained. This is because at each iteration of Alg. 4.1, the solution of the subproblem solved by Newton method (66) already provides a Euclidean distance matrix.

6. Conclusion and Future Research. In this paper, we studied the Newton method for computing the nearest Euclidean distance matrix from a given predistance matrix or dissimilarity. Our theoretical analysis is mainly on the unweighted case (3). The main result is that the Newton method is quadratically convergent. This main result also holds for the diagonally weighted problem (62), which naturally arises from a majorization approach for the \( H \)-weighted problem (4). Our numerical experiments showed that the Newton method is extremely efficient even for large scale problems. This research also provides a solid foundation for other important problems.

One such problem is the embedding problem (6) and its \( H \)-weighted version:

\[
\min \frac{1}{2} \|H \circ (X - D)\|^2 \quad \text{s.t.} \quad X \in S_h^n \cap K^n_+ \quad \text{and} \quad \text{rank}(JXJ) \leq r.
\] (70)

In distance geometry models for molecular conformation, distances are often known to be contained in box, i.e., \( l_{ij} \leq D_{ij} \leq u_{ij}, \ 1 \leq i,j \leq n \). "The difference between
the upper bound and lower bound reflects the accuracy with which the data is known. To reflect this accuracy in the algorithms, it is important that weighted models be considered.” For more explanation on the above statement, see [21, P. 114], which recommends $H_{ij} = 1/(1 + 10(|u_{ij} - l_{ij}|))$. The finding in this paper opens a new avenue for using the Newton method to (70) through a penalty approach (i.e., penalizing the rank constraint). As rightly pointed out by one referee, the rank constraint would “break the convexity and duality gap could arise”. The latest research shows that the duality gap vanishes under reasonable conditions and the Newton method developed in this paper plays a very important role in solving (70) (see [39] for details).

For the $H$-weighted problem (4), we proposed a majorization approach, which at each iteration solves a diagonally weighted problem. As seen from Tables 2 and 3, this approach sometimes took a good number of iterations to reach the required accuracy. Given the inner problem can be efficiently solved, one area we plan to investigate is to look at strategies to improve the efficiency of the majorization approach as well as other approaches.

Acknowledgments. The author would like to thank Prof. K.-C. Toh of National University of Singapore for his help on using QSDP solver on the test problems. The author also wishes to thank the two referees for their valuable comments and constructive suggestions, which have significantly improved the quality of the paper.
