Building Traceable Event-B Models from Requirements

Eman Alkhammash, Asieh Salehi Fathabadi, Michael Butler, and Corina Cîrstea

Abstract: Constructing traceable Event-B models from requirements is crucial in the system development process. It enables the validation of the model against the requirements and allows to identify different refinement levels, which is a key to successful formal modelling with a refinement-based method. Our objective is to present an approach based on the use of semi-formal structures to bridge the gap between requirements and Event-B models and retain traceability to requirements in Event-B models. The presented approach makes use of the UML-B and Atomicity Decomposition (AD) approaches. UML-B provides UML graphical notation that enables the development of an Event-B formal model, while the AD approach provides a graphical notation to illustrate the refinement structures and assists in the organisation of refinement levels. The intent of this paper is to harness the benefits of the UML-B and AD approaches to facilitate constructing Event-B models from requirements and provide traceability between requirements and Event-B models.

Keywords: Event-B, Traceability, UML-B, AD

1 Introduction

We present an approach for incrementally constructing a formal model from informal requirements with the aim to retain traceability to requirements in models. The approach helps to identify the modelling elements from requirements, assists the construction of a formal model, and facilitates layering the requirements and mapping the informal requirements to traceable formal models. Traceability supports the process of validation of the model against the requirement document and allows missing requirements to be easily accommodated in the model.

Our approach is based on the Event-B formal method [Abr10]. Event-B is a refinement-based formal method with good tool support for developing various kinds of systems. Event-B covers a range of approaches to support a formal modelling.

In our approach, we make use of UML-B [SB06] and Atomicity Decomposition (AD) [But09a, FBR12] approaches. UML-B provides a graphical modelling environment (UML notation) which enables the development of an Event-B formal model. The AD approach provides a graphical notation to structure refinement and describes the ordering between events. The visual view of the system provided by the UML-B and AD assists in the development of the refinement strategy before the actual work on modelling is performed. The combined AD diagrams, which show the overall refinement structure of the system, can be modified until an acceptable refinement structure is reached. In addition, the AD approach provides several constructor patterns that can be used to manage the flow of events and define event ordering. Moreover, Event-B models corresponding to AD diagrams and UML-B diagrams can be generated automatically by the AD and UML-B tool.
The presented approach comprises of three stages, which are shown in Figure 1. The first step in our approach is requirement classification. Requirements are classified based on Event-B components. The classification consists of five classes: data-oriented, constraint-oriented, event-oriented, flow-oriented, and others. Data-oriented requirements represent attributes and relationships between attributes, constraint-oriented requirements represent conditions that must remain true in the system, event-oriented requirements represent the activities of the system and its components, flow-oriented requirements represent relationships between events, and “others” represents other requirements that do not fit into the previous classes.

The second step consists of three main stages. Firstly, we use semi-formal artifacts described using UML-B, AD diagrams and structured English to represent requirements. The UML-B is used to represent data-oriented requirements. The AD is used to represent flow-oriented requirements. The structured English is a way of breaking down constraint and event-oriented requirements into shorter sub-requirements and mapping each sub-requirements to the proper class (constraint or event-oriented). The semi-formal artifacts serve as an intermediate representation that map requirements to Event-B formalism. Representing requirements using semi-formal artifacts is reasonably simple, and at the same time the movement from the semi-formal artifacts to the Event-B is straightforward. Secondly, we merge the fragmented structured English of a single event together to facilitate tracing the event components. Thirdly, we combine AD diagrams and use these diagrams to assist the process of developing the refinement strategy.

The third step of the proposed approach is to use the UML-B tool and the AD tool to generate Event-B models and also write manually the corresponding Event-B from the structured English representation.

This paper is structured as follows: Section 2 gives an overview of the Event-B formal method, UML-B, and AD approach. The description of the presented approach is introduced in Section 3. Section 4 introduces some related works in requirement traceability. Conclusions are drawn in Section 5 and Future work is presented in Section 6.

2 Preliminaries

2.1 Event-B

Event-B is a formal method developed by Jean-Raymond Abrial, which uses set theory and first order logic to provide a formal notation for the creation of models of discrete systems and the undertaking of several
refinement steps. An abstract Event-B specification can be refined by adding more detail and bringing it closer to an implementation. A refined model in Event-B is verified through a set of proof obligations expressing that it is a correct refinement of its abstraction. Event-B may be used for parallel, reactive or distributed system development, and has shown success in the development of different complex real-life systems [But09b, BA05]. The Event-B notation contains two constructs: a context and a machine. The context is the static part of a model in which the data of the model (sets, constants and axioms) is defined. The dynamic and functional behaviour of a model is represented in the machine part, which includes variables to describe the states of the system, invariants to constrain variables, and events to trigger the behaviour of the machine.

Rodin [ABHV06, ABH10] is a platform for modelling and proving in Event-B models. Rodin exhibits many features and can be extended further with supportive plug-ins. Relevant to this work is the Atomicity Decomposition (AD) plug-in, which provides a graphical notation to structure refinement and to manage flows in Event-B models. An overview of the AD approach is given in Section 2.3.

2.2 UML-B

UML-B is a diagrammatic notation based on UML and Event-B. It provides a graphical modelling environment that allows the development of an Event-B formal model through the use of UML graphical notation. There are four types of UML-B diagrams, namely package diagrams, context diagrams, class diagrams and state machine diagrams. Package diagrams represent the structure and the relationships between Event-B contexts and machines. A context diagrams describes the context part of an Event-B model. describes only the context components such as constants. Class diagram and state machine diagrams describe state and behaviour and are used in Event-B machines. Class diagrams in UML-B may contain attributes (variables), associations (relationships between two classes), events and state machines (transitions between events). State machine diagrams describe the behaviour of instances of classes as transitions linked to events.

UML-B assimilates the notion of refinement. It is possible to introduce a class in a refined machine that refines a class of its abstract machine. A refined class can keep all attributes of its abstract class, corresponding to the case where a refined machine keeps all the variables of an abstract machine. It is also possible that a refined class drops some of the attributes of the abstract class, corresponding to the case of removing variables through performing data refinement. Moreover, a refined class can introduce new attributes in the class diagram, corresponding to the case of introducing new variables in the refinement levels.

A UML-B tool [SB08] has been developed for the Rodin platform which can be used to generate an Event-B model corresponding to a UML-B development.

2.3 Atomicity Decomposition Approach

Although refinement in Event-B provides a flexible approach to modelling, it has the weakness that it cannot explicitly represent the relationships between abstract events and new events which are introduced in a refinement level. The Atomicity Decomposition (AD) approach addresses this limitation. The idea is to augment Event-B refinement with a graphical notation that is capable of representing the relationships between abstract and concrete events explicitly. Using the AD approach has another advantage, namely that it allows event ordering to be represented explicitly. Figure 2 illustrates these two features of the AD graphical notation. Assume machine M1 on the left hand side of Figure 2 refines some machine M0 which contains the abstract specification of AbstractEvent. The machine M1 encodes its control flow (ordering between Event1 and Event2) via guards on the events. This control flow is made explicit in the AD diagram presented on the
Building Traceable Event-B Models from Requirements

![Atomicity decomposition diagram](image)

Figure 2: Atomicity decomposition diagram

right hand side. This diagram explicitly illustrates that the effect achieved by AbstractEvent at the abstract level, machine M0, is realized at the refined level, machine M1, by the occurrence of Event1 followed by that of Event2. The ordering of the leaf events is always from left to right (this is based on JSD diagrams [Jac83]). The solid line indicates that Event2 refines AbstractEvent while the dashed line indicates that Event1 is a new event which refines skip. In the Event-B model of machine M1 on the left hand side, Event1 does not have any explicit connection with AbstractEvent, but the diagram indicates that we break the atomicity of AbstractEvent into two sub-events in the refinement.

The parameter par in the diagram indicates that we are modelling multiple instances of AbstractEvent and its sub-events. Events associated with different values of par may be interleaved, thus modelling interleaved execution of multiple processes. The effect of an event with parameter par is to add the value of par to a set control variable with the same name as the event, i.e., \(par \in \text{Event1}\) means that Event1 has occurred with value \(par\). The use of a set means that the same event can occur multiple times with different values for par. The guard of an event with parameter par specifies that the event has not already occurred for value \(par\) but the previous event has occurred, e.g., the guard of Event2 says that Event1 has occurred and Event2 has not occurred with value \(par\).

3 Steps for Constructing Traceable Event-B Models

This paper presents an approach for constructing traceable Event-B models using UML_B and the AD approach. We do not address the question of how requirements are arrived at. Requirements could have been arrived at using use cases [KG12]. In use cases, the system’s functionality is described through structured stories in easy-to-understand text form, from which requirements can be derived. Our objectives are to provide a link between requirements and formal models and to facilitate building traceable Event-B formal models from requirements. The following subsections describe the steps proposed to achieve these goals.

Proc. AVoCS 2013 4 / 15
3.1 Step 1: Classify Requirements

We classify requirements into the following five classes as stated above, based on the structure of Event-B models: data-oriented requirements, constraint-oriented requirements, event-oriented requirements, flow requirements, and other requirements. Each requirement can be classified into at least one category. A detailed description of the requirement classification, with examples of lift controller requirements taken from [Rob10], is given below.

**Data-oriented requirements**: requirements that describe attributes of nouns and the relationships between nouns. Here are three examples of this requirement class:

| REQ1   | Each floor has one button for requesting travelling to another floor |
| REQ2   | The lift-door can be closed or opened                              |
| REQ3   | The lift can be moving or stopped                                  |

The nouns “floor” and “button” in the requirement *REQ1* are identified as data-oriented requirement. The noun “lift-door” and the attributes “closed” and “opened” in the requirement *REQ2* are also identified as data-oriented requirement since they describe states of the door. Similarly, the noun “lift” and the attributes “moving”, and “stopped” in the requirement *REQ3* are identified as data-oriented requirement since they describe states of the lift.

**Constraint-oriented requirements**: requirements that describe properties about the data that should always remain true. They are normally identified by keywords such as *never, must not, always* etc.

The following is a constraint-oriented requirement:

| REQ4   | The lift door of a moving lift must be closed                     |

Requirement *REQ4* describes a system property relating the position of the lift door and the lift motion.

**Event-oriented requirements**: requirements that describe a function or activity of the system or its components. Events are normally identified by the “verbs”, such as the following requirement:

| REQ5   | People on a floor press a button to request a lift               |

The verb “request” denotes that *REQ5* is of event-oriented type. The part of an event-oriented requirement that describes conditions under which an event can happen is called a guard requirement, whereas the part of an event-oriented requirement that describes how the data is going to change is called an action requirement.

**Flow requirements**: requirements that describe the interaction between operations. We can classify flow requirements generally into three types: sequence requirements which describe sequencing between operations, selection requirements which describe “if-then-else” structure to indicate the selection between two or more operations, and repetition requirements which describe the iteration of a particular operation multiple times. Table 1 provides examples of flow requirements:
### Table 1: Description of flow requirements

<table>
<thead>
<tr>
<th>Flow requirements</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequencing require-ments</td>
<td>REQ6 The floor door closes before the lift is allowed to move</td>
<td>The relationship between the door closing operation and the lift moving operation can be seen as a sequence. After the lift-door closes, the lift is allowed to move.</td>
</tr>
<tr>
<td>selection require-ments</td>
<td>REQ7 If a lift is stopped then the floor-door for that lift may be open</td>
<td>In this requirement the lift door can be either opened or left closed when the lift is stopped.</td>
</tr>
<tr>
<td>repetition require-ments</td>
<td>REQ8 There might be more than one external floor request in a particular floor, the lift will respond to them (stop) only once</td>
<td>Here, “more” indicates the iteration of the floor request operation.</td>
</tr>
</tbody>
</table>

The above classification seems to be more prevalent to many case studies. Nevertheless, flow requirements are not restricted to this classification, and other classes can be identified by analysing more case studies.

**Other requirements**: other requirements that do not fit into the previous classes can be considered in this class. This includes requirements that are very hard to model in Event-B, such as requirements that represent fairness properties or timing properties.

### 3.2 Step 2: Construct Semi-formal Artifacts and Develop Refinement Strategy

This step comprises three stages, described in what follows.

#### 3.2.1 Stage 1: Use semi-formal artifacts (UML-B, AD, and Structured English)

In the first stage, requirements are represented in a semi-formal notation depending on their type:

- **Data-oriented requirements** are represented using UML-B diagrams: nouns or attributes are represented using class diagrams, relationships between nouns are represented using UML-B associations, and transitions between attributes are represented using state machine diagrams.

- **Constraint and Event-oriented requirements** are represented using structured English. The structured English is a way of breaking down constraint and event requirements into smaller requirements and mapping each sub-requirement into their requirement identifiers to facilitate the tracing of requirements.

The structured English representation for constraint-oriented requirements is of the following form:

```
constraint : < constraint requirement > -----> <REQ>
```

The structured English representation for event-oriented requirements is of the following form:

```
event name

guard : < guard requirement > -----> <REQ>

action : < action requirement > -----> <REQ>
```
In the above notation, the arrow is used for tracing back to the original requirement, and \(REQ\) denotes the requirement identifier.

- **Flow requirements** are mapped to the appropriate AD diagram according to Table 2 which summarises the behaviour of the AD patterns: sequence requirements are mapped to sequence/and diagrams, selection requirements are mapped to or/xor diagrams, and repetition requirements are mapped to loop/all/some replicator diagrams.

<table>
<thead>
<tr>
<th>pattern</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence-/and-constructor</td>
<td>execute events in a sequence. The difference between sequence- and and-constructor is that and-constructor executes all available events in any order, while the sequence constructor executes events in a particular order.</td>
</tr>
<tr>
<td>or-constructor</td>
<td>execute one or more events from two or more available events, in any order</td>
</tr>
<tr>
<td>xor-constructor</td>
<td>execute exactly one event from two or more</td>
</tr>
<tr>
<td>loop pattern</td>
<td>execute an event zero or more times</td>
</tr>
<tr>
<td>all-replicator</td>
<td>execute an event for all instances of a defined set</td>
</tr>
<tr>
<td>some-replicator</td>
<td>execute an event for one or more (some) instances of a defined set</td>
</tr>
<tr>
<td>one-replicator</td>
<td>execute an event for one instance of a defined set</td>
</tr>
</tbody>
</table>

Table 2: Description of the AD patterns

Representing requirements into graphical/structured English notation provides an intermediate level of tracing information and enables the validation of the model against the requirements.

Assuming that requirements are analysed based on the described requirement classification, the following examples illustrate how to represent each requirement class in a graphical or structured English notation.

The data-oriented requirement **REQ1** is represented as follows:

![Figure 3: The class diagram for REQ1](image)

The class **Floor** consists of the association **FloorButton** of type **Button** which is defined as a boolean that indicates whether there is a request for the lift to stop at that floor. The multiplicity property for the association **FloorButton** specifies a many-to-one relationship (i.e., total function). That is, there are \(n+1\) floors and a boolean for each floor to indicate whether there is a request for the lift to stop at that floor.

The data-oriented requirement **REQ2** is represented using the state machine in Figure 4, which shows two states, “open” and “close”, and two transitions **OpenLiftDoor** and **CloseLiftDoor**.
The data-oriented requirement **REQ3** is represented using the state machine in Figure 5, which shows two states, “stopped” and “moving”, and two transitions *LiftStop* and *LiftMoving*.

The constraint-oriented requirement **REQ4** is represented as follows:

```
constraint: The lift door of a moving lift must be closed
```

The event-oriented requirement **REQ5** is represented as follows:

```
event RequestFloor
guard: a request at floor f is made
action: new request is added to the pool of pending requests
```

The flow requirements **REQ6, REQ7** and **REQ8** can be represented as follows:

Figure 6a shows that the behaviour of the *LiftMove* event is exhibited by executing the *CloseLiftDoor* event followed by the *LiftMove* event. The xor-constructor pattern in Figure 6b indicates that the behaviour of the *LiftStop* event in the root node is exhibited by executing the *LiftStop* event followed by either the *OpenLiftDoor* event or the *NotOpenLiftDoor* event. The latter event has skip action and is used to skip from applying any change to the lift-door status; this is because the “xor” pattern forces the execution of only one leaf. Finally, the behaviour of the *LiftStop* event in Figure 6c is exhibited by executing the *RequestFloor* event multiple times followed by the *LiftStop* event.
3.2.2 Stage 2: Merging structured English of a single Event

It is possible that two or more structured English requirements refer to a single event. If such requirements exist, we merge them here. However, in this small case study we do not have requirements that refer to a single event. An example of this aspect is given by the following two requirements:

<table>
<thead>
<tr>
<th>TSK1</th>
<th>Tasks can be created and destroyed</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSK2</td>
<td>Tasks are assigned priority when created</td>
</tr>
</tbody>
</table>

Requirements TSK1 and TSK2 are event-oriented requirements that refer to a Task_Create event. The structured English of the requirements TSK1 and TSK2 need to be merged in this step.

3.2.3 Stage 3: Develop Refinement Strategy

Here we combine the AD diagrams developed in the first stage in order to organise the refinement levels. Flow is one criterion that can be considered in devising the refinement strategy. The nature of the requirements, the nature of the architecture that the refinement is aiming towards and the nature of the data types being refined are other important criteria that might come before the flow criterion since they may influence the flow requirements. The visualisation of the overall structure of the system gives more insight into the development of the refinement strategy before any Event-B modelling is carried out. It allows the developer to illustrate visually the hierarchy of the model based on the important criteria the developer is aiming at, and also helps to control the size of the model and view the number of events in each refinement level. Another advantage of the diagrammatic view of the refinement strategy is that it allows to visualise event dependencies and structure/variable dependencies. For example, in Event-B, events that update a particular variable should be introduced in the same modelling level. This is a restriction imposed by Event-B and is often only discovered during the modelling activity. The visual view of events given by the AD diagrams helps to deal with this restriction before modelling. Moreover, using this view, the developer can first introduce the basic properties of the system, and then introduce more complex properties that depend on the basic properties in the refinement levels. For instance, the developer of a real-time operating system (OS) can introduce basic properties of the processes used by the application developer in the abstract model, and in deep refinement levels the developer can introduce complex properties that are used by the real-time OS to handle the processes.

Figure 7 shows the refinement levels for the lift controller case study.

![Figure 7: The combined AD diagrams for the lift controller](image-url)
In the abstract level, we decided to model two abstract events: AbstractLiftStop and AbstractLiftMove. We use a sequence pattern to indicate the sequencing between the abstract events. In the first refinement, we decided to combine the tree structure with root AbstractLiftStop that corresponds to the AD diagram in Figure 6b and the tree structure with root AbstractLiftMove that corresponds to the AD diagram in Figure 6a. Finally, we make use of the AD diagram given in Figure 6c to refine the LiftStop1 event. We note that, because of a restriction in the AD tool, event names in the combined AD diagrams are changed slightly from their names in the individual AD diagrams. The AD tool automatically generates flags and gluing invariants according to event names. The generated gluing invariants show the relationships between the abstract flags and concrete flags. Therefore, the flag names for the abstract events are required to be different from the flag names for the refined events.

### 3.3 Step3: Construct Formal Models

In this step, we use the UML-B and AD tools to convert the diagrams of step 2 to Event-B notation. We also manually convert the structured English representation into Event-B.

The Event-B specification of the requirements REQ1, REQ2, and REQ3, generated from the class and state machine diagrams, is given below:

```plaintext
SETS
  Floor_SET, Button_SET, door_STATES, lift_STATES
CONSTATS
  open
close
moving
stopped
AXIOMS
  open.type open ∈ door_STATES
close.type close ∈ door_STATES
distinctStates_door_STATES partition(door_STATES, {open}; {close})
distinctStates_lift_STATES partition(lift_STATES, {moving}; {stopped})
End
```

Figure 8: Sets, constants and axioms generated from the class and state machine diagrams

Figure 3 contains two classes represented by the variables Floor and Button. These variables are defined as subsets of Floor_SET and Button_SET, that represent the set of all possible instances for each class. The UML-B associations are translated into variables whose type is a function from the class set to the attribute type. Hence, FloorButton in Figure 3 is translated into a function from Floor set to Button set. The multiplicity of an association determines the type of the function: partial, total, injective etc. Here (0.. * → 1..1) is translated into a total function that maps Floor to Button. The state machine in Figure 4 is translated into Event-B as disjoint sets representation as shown in axiom distinctstates_door_STATES. States open and close are translated into constants of type door_STAT ES.

Each transition is translated into an event whose guard specifies the source state and whose actions specify its target state. Hence, OpenLiftDoor is an event that changes the lift door from close state to open state and CloseLiftDoor is an event that changes the lift door from open state to close state. The state machine of Figure 5 is translated in a similar manner to the state machine of Figure 4.
The Event-B specification written manually for the requirement \textit{REQ4} is:

\[ \forall f. f \in \text{dom} \(\text{door}\) \land \text{lift} = \text{moving} \implies \text{door}(f) = \text{close} \]

Also, the structured English for the requirement \textit{REQ5} can be formalised manually as follows:

\begin{verbatim}
  event RequestFloor
  where
    grd1 f \in Floor \setminus request
  then
    request := request \cup \{f\}
\end{verbatim}

According to the loop pattern rule, the \textit{RequestFloor} event can be executed zero or more times before the execution of the \textit{LiftStop} event. Thus, the \textit{RequestFloor} event does not have a variable and an action to record the loop execution. It only has one guard \texttt{LiftStop2 = FALSE} that allows zero executions of the loop event. We need to make a slight change to this pattern to allow the \textit{RequestFloor} event to be executed at least one time before the execution of the \textit{LiftStop} event. This can be achieved by adding manually a boolean flag...
RequestFloor together with the action RequestFloor:=TRUE in the RequestFloor event instead of the guard LiftStop2 = FALSE in the RequestFloor event. Also we add the guard RequestFloor=TRUE to the LiftStop event to check the execution of the RequestFloor event. That way, RequestFloor must be executed at least one time before the LiftStop event. This modification can be considered as a new repetition pattern that allows the execution of an event one or more times before the execution of other events. Clearly, there is a need to investigate different AD patterns for different requirement types.

The following gluing invariant is generated by the AD tool for the leaf with solid line in the loop AD diagram in Figure 6c:

\[
\text{LiftStop2} = \text{LiftStop1}
\]

The gluing invariant defines the relationship between the abstract flag LiftStop1 and the concrete flag LiftStop2 and is used to discharge the refinement proof obligation.

Requirements REQ6 and REQ7 are dealt with in a similar way. The generated Event-B models from AD diagrams and UML-B diagrams can be combined using shared-event composition [SB11]. This concludes the application of the general approach described in this section.

We note that the presented approach has been applied also to a larger case study of 32 requirements. The case study is an Event-B specification for queue management in FreeRTOS. FreeRTOS [Bar10] is an open source, mini kernel developed by Richard Barry to serve real-time application requests. Data transfer is established by means of queues. Queues are mechanisms used to serve communication between a task-to-task or a task-to-Interrupt Service Routine (ISR) [Bar10]. The requirement categorisation for the queue management case study was useful: 9 requirements were classified as data-oriented requirements, 3 as constraint-oriented requirements, 20 as event-oriented requirements and 7 as flow requirements. Four conclusions were drawn from the application of our approach to the queue management case study. Firstly, we found that flow requirements can sometimes be extracted from more than one requirement. For example, the sequencing between the event responsible for sending an item successfully to a queue in the requirement QUE1 and the event responsible for removing the highest-priority task from the collection of receiving task-waiting in the requirement QUE2.

| QUE1 | A task can only send items to a queue when there is enough room in the queue |
| QUE2 | When a queue becomes available (there is an item in the queue to be received) then the highest-priority task waiting for item to arrive on that queue will be removed from the collection of receiving task-waiting |

Secondly, AD patterns do not cover all possible flows, we sometimes need to modify them to represent the exact flow we are looking for, or even explore some new patterns. For example, one might need to represent “one or more” executions of an event. This is currently not supported by the existing patterns, however, the loop AD pattern together with an additional manual flag can be used to represent this particular case. Thirdly, it is possible that a particular event becomes a leaf in different AD diagrams. In some cases however, it is necessary to change the name of the recurrent leaf to avoid an invalid combination of AD flags. Assume that an event \(x\) is a leaf in a sequence diagram and also a leaf in an “xor” diagram. If this leaf has the same name in both trees, then the AD tool will generates “xor” flags and sequence flags for the event \(x\). Mixing flags together in a single event can result in mis-behaviour of the intended flows. Overall, further investigations should be considered to evaluate the presented approach and to explore more useful patterns for managing
flows. Finally, the proposed approach allows different requirements to be represented in the same modelling element (variable, event, etc). For example:

<table>
<thead>
<tr>
<th>TSK3</th>
<th>Task is an object in FreeRTOS</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSK4</td>
<td>Task can send an item to a queue</td>
</tr>
</tbody>
</table>

Task is shared variable between the requirement TSK3 and the requirement TSK4. The requirement TSK3 is classified as a data-oriented requirement whereas TSK4 is classified as an event-oriented requirement.

4 Related Works

This section presents three works in the area of requirements traceability. SOFL (Structured Object-Oriented Formal Language) \cite{Liu04} is an approach that uses graphical and textual formal notation for system construction. It is an integration of Data Flow Diagrams, Petri Nets, and VDM-SL. The graphical and textual formal notation serve as a good communication mechanism between a user and a developer. One of the main differences between our work and \cite{Liu04} is that our work makes use of structured English and graphical notation represented in UML-B and the AD approach to bridge the gap between requirements and Event-B models, whereas the semi-formal artifacts used in the SOFL approach are used to document requirements.

Jastram et al \cite{JHLG10} presented another approach to achieving requirement traceability. They structure the requirements based on WRSPM. WRSPM is a model used for the formalisation of system requirements. It differentiates between phenomena (state space and transitions of the system) and artifacts (the restriction on states and transitions). The artifacts are classified into groups: Domain Knowledge (W), Requirements (R), Specifications (S), Program (P) and Programming Platform (M). Once the requirements are structured using WRSPM, the second step is to use a formal model for system specification. WRSPM elements are mapped to Event-B. This mapping provides a way for traceability between requirements and the Event-B model. They distinguish three types of possible traces: evolution traces, explicit traces, and implicit traces. Evolution traces are explored through the requirement evolution over time. Explicit traces are used to link each non-formal requirement to a formal statement. Implicit traces are discovered via refinement relationships, references to model elements or proof obligations. The main difference between our approach and the \cite{JHLG10} approach is that the latter focuses more on traceability and uses intermediate constructs based on WRSPM to provide traceability between requirements and Event-B models. On the other hand, the intermediate constructs which we use are based on requirement classification derived from Event-B components. In effect, the process of converting the semi-formal artifacts into an Event-B model are straightforward, as this is done using the UML-B and AD tools. Moreover, our approach focuses not just on building Event-B models but also on traceability.

Yeganefard and Butler \cite{YB12} described an approach for structuring requirements of control systems to facilitate refinement-based formalisation. The approach has three stages: In the first stage, requirements are categorised into monitored (MNR) requirements, commanded (CMN) requirements and controlled (CNT) requirements. The second step lays on layering requirements by modelling one feature in each refinement level; the developer chooses which feature to model in each refinement level. They suggest modelling the main role of the system with a minimum set of requirements in the very abstract model. The third step is based on revising the requirement document and the formal model to investigate any inconsistent, ambiguous or missing requirements. Comparing our work with \cite{YB12}, the approach used in \cite{YB12} is specific to control systems whereas the approach of this paper is based on Event-B structures. We also think that structuring
Building Traceable Event-B Models from Requirements

refinement levels based on a textual requirement document is difficult. We believe that the visualisation of Event-B components using AD diagrams gives a clear overview of the whole system and helps decide which feature to model in each refinement level. It is possible to combine our approach and that of [YB12] to obtain more effective guidelines for developing traceable Event-B models for control systems.

5 Conclusions

We presented an approach which facilitates constructing Event-B models and provides clear traceability between requirements and the Event-B model. The approach is based on the use of the UML-B and AD approaches. The UML-B provides UML graphical modelling environment that allows the development of an Event-B model, whereas the AD approach provides a graphical notation to structure refinement and manage flows in an Event-B model.

Applying UML-B at the requirement level facilitates the mapping from data-oriented requirements to Event-B model. Event-B models of the UML-B diagrams are generated automatically by the UML-B tool. On the other hand, applying the AD approach at the requirement level assists a developer in the process of deciding which features to be modeled in each refinement step. Moreover, the Event-B model is generated automatically by the AD tool, which reduces the burden of the manual work especially in the development of complex systems. The combined AD diagrams provide insight into the overall visualisation of the refinement structure and demonstrate the relationships between events even before any model is written.

6 Future work

The application of the proposed approach to several case studies is the primary goal of future work. In this paper we describe one kind of constraint-oriented requirements, namely requirements on the system being developed, such as requirement REQ4. We also need to investigate another type of constraint-oriented requirements, which describe assumptions on the environment, such as the following requirement:

| REQ9 | The lift can transition from stopped to moving-up or moving-down, from moving-up or moving-down to stopped, but not from moving-up to moving-down or vice versa |

Exploring the scalability of the graphical models is another direction for future work. The visual view of the refinement strategy provides some support for scalability: the ADD diagrams are hierarchical and it always possible to partition the diagram into sub-hierarchies; UML-B class diagrams can be also layered through refinement. Further work is needed to investigate the scalability issue. Finally, further investigation of several AD patterns is necessary to support a larger class of flow requirements.
