Abstract: We report fabrication of the first low-loss, broadband 37-cell photon bandgap fiber. Exploiting absence of surface modes and low cross-talk in the fiber we demonstrate mode division multiplexing over three modes with record transmission capacity.

OCIS codes: (060.4005) Microstructured fiber; (060.0060) Fiber optics and optical communications.

1. Introduction
Hollow core photonic bandgap fibers (HC-PBGFs) have long been viewed as interesting candidates for data transmission because of their low nonlinearity and potential for ultralow loss. However, issues associated with surface modes (SMs), which substantially reduce the usable fiber bandwidth, along with concerns about the number of higher order modes have discouraged work in this area, despite losses as low as 1.7dB/km reported in 2004 [1]. Recently, however, 19-cell (19c) HC-PBGFs with wide bandwidths (>150nm) and a few dB/km loss [2, 3] have been demonstrated to enable high capacity, low-latency single-mode data transmission at both 1.5µm and 2µm [4,5].

A possible solution to further reduce surface scattering -the primary loss mechanism in these fibers- is to decrease the optical field overlap with the glass, e.g. by enlarging the core size from 19 to 37 cells (37c). HC-PBGFs with bigger cores, however, present a number of challenges, including stricter fabrication tolerances, difficulties associated with a potentially higher number of surface modes and an increased number of core guided modes [6], which are more narrowly spaced and thus more susceptible to perturbation-induced coupling. In principle, mode coupling along the fiber can be unraveled using Multiple Input Multiple Output (MIMO) techniques, so that separate modes can be used to transmit independent channels, making the intrinsic multi-mode nature of HC-PBGFs a feature to exploit rather than a problem. However, the very first experiments of mode division multiplexing (MDM) in HC-PBGFs have raised the question as to whether high capacity MDM might be possible at all [7, 8].

In this work, we report the fabrication of the first ever low-loss, wide-bandwidth 37c HC-PBGF, a fundamental step towards achieving ultralow-loss HC-PBGFs. The fiber, obtained by applying similar core-surround engineering as previously demonstrated for 19c fibers [2,3], has a low minimum fundamental mode loss of 3.3 dB/km at 1550 nm and a wide 3-dB bandwidth of ~85 nm centered in the C-band. By using mode multiplexing techniques, we characterize in detail the fiber’s modal properties, showing that it supports significantly less modes than would have been expected and that at least the LP01 and LP11 modes have properties compatible with MIMO-based MDM.

To prove it, we report the first transmission of polarization and wavelength division multiplexed (DWDM) signals over 3 modes in such a fiber. Using 96 DWDM channels, 3 MDM modes and a 16-level quadrature amplitude modulation (16-QAM) we achieve a total data rate of 73.7Tb/s, which sets a new transmission record for HC-PBGFs.

2. Fabrication and characterization of 37-cell HC-PBGF
The HC-PBGF (shown in the inset of Fig.1a) was fabricated by omitting 37 capillaries in the stack and by accurately controlling differential pressures during both drawing stages. Its cladding pitch and relative hole size (4.4 µm and 0.97, respectively) provide a ~300 nm wide bandgap. Although controlling SM position and number is more challenging than with 19c fibers, we managed to achieve a fiber with only two groups of SMs, which we successfully located at either sides of the C-band, providing an overall ~85nm wide low loss bandwidth (Fig.1e).

Despite a large core diameter of 37µm, which is required for low loss operation but is in principle able to support as many as 80 core modes, S2 measurements indicate that only 16 modes divided in 5 mode groups (even fewer than in a previously reported 19c HC-PBGF [2]) are guided with low loss in our fiber. S2 cutback analysis (traces at 9m and 2m shown in Fig.1b) reveals that modes beyond the LP02 experience high propagation losses (estimated at ≥6 dB/m) likely due to coupling to lossier cladding modes; a more detailed investigation is still underway.
In this work we focus on the characterization of three lowest order spatial modes (LP₀₁, LP₁₁a, LP₁₁b), which are predicted to have the lowest propagation losses [9], and present a detailed description of their properties. To selectively launch the three individual modes we employed the phase-plate based mode multiplexer (MMUX) illustrated in Fig.1a. Light from a supercontinuum (SC) source was split in three paths, encoded in the required mode patterns and coupled into 310 m of 37c HC-PBGF via a telecentric lens arrangement. The SC laser provided a high average power which was required to compensate for the high MMUX insertion losses.

Time-of-flight (ToF) measurements [2] using sub-ps pulses from a mode-locked laser at 1550 nm and a 10 GHz bandwidth sampling oscilloscope were employed during the modal characterization to optimize the launch of each individual mode. Typical results are shown in Fig.1c: the DGD of the LP₁₁ and LP₂₁ modes was estimated at 4-5ps/m and 10-12ps/m, respectively, in good agreement with S² results. Note that DGD values are roughly 50% smaller than in a 19c fiber [2,3]. The extinction ratio provided at launch by our MMUX was about 20 dB. For LP₁₁ mode launch we observed strong coupling between the two spatial orientations and a plateau of distributed scattering [10] of about -20dB to both LP₀₁ and LP₂₁ modes. Modal cross-coupling is expected to decrease as the fiber loss is reduced since the two effects have the same underlying physical mechanism in HC-PBGFs. The wavelength dependence of the DGD (Fig. 1d) indicates chromatic dispersion around 7 and 18 ps/nm/km for LP₀₁ and LP₁₁ modes, respectively.

Through a careful cutback from 310m to 20m the mode-specific spectral loss (shown in Fig. 1e) was measured – to the best of our knowledge the first such measurement in a HC-PBGF. All curves present two distinct peaks due to SM anticrossings which, as predicted from theory but never before shown experimentally, are mode dependent and
shifted ~10nm to longer wavelengths for the LP11 modes as compared to the LP01 mode. The minimum loss values for LP01 and LP11 are 3.3±0.8 and 7.4±0.8 dB/km, respectively, at 1550nm. The higher loss of the LP11 modes derives from a higher overlap with the air-glass interfaces which causes stronger scattering, and the value of the differential loss between LP01 and LP11 is in good agreement with numerical predictions [9]. Despite its large core, the fiber is still very robust to bending. Fig. 1f shows the spectral change in transmission after a short section near the output end of the HC-PBGF was coiled into 13 loops of 16mm radius. While some bend-induced loss increase (and associated bandwidth decrease) was observed at or near the SMs, no measurable change was observed for any core mode in their respective low loss region, providing further evidence of the importance of suppressing SMs.

3. Demonstration of Mode Division Multiplexed transmission

Exploiting the excellent modal qualities of this novel 37c HC-PBGF we demonstrated the feasibility of large capacity transmission employing the MDM transmission setup described in [11]. The WDM system included 96 external cavity lasers running on a 50 GHz ITU grid in the extended C-Band (1528.77-1566.72 nm), modulated with 256 Gb/s dual-polarization 16-level quadrature amplitude modulation (DP-16QAM). The input signal was split into three equal-power replicas, delayed with respect to one another for de-correlation and mode-division multiplexed using the MMUX of Fig.1a. The resulting 73.7 Tb/s WDM-MDM signal was transmitted over 310 m of HC-PBGF, after which the modes were demultiplexed. The channel under test (CUT) was selected using 50 GHz optical filters and received with three coherent receivers connected to time-synchronized digital sampling scopes; the recorded data was processed offline using a 6×6 MIMO digital signal processing algorithm to decouple the signals. Fig. 2 shows the bit error rate performance after transmission for all 96 channels, the received spectrum at the LP01 port and the received constellation for the channel running at 1550.12 nm. As can be observed, all channels are well below the FEC-limit at 2.4×10^{-2} [12], again providing compelling evidence of excellent fiber modal characteristics.

4. Conclusions

We have reported the first ever detailed modal characterization of a novel 37c HC-PBGF boasting a low minimum fundamental mode loss of 3.3dB/km at 1550nm and an 85nm wide 3-dB bandwidth. The mode-dependent spectral and bend loss of its 3 lowest order modes were measured along with their propagation and cross coupling properties. Absence of SMs and low cross-talk are pre-requisites for high capacity MDM-DWDM transmission in a HC-PBGF, which we demonstrate here for the first time. Our total data rate of 73.7 Tb/s sets a new transmission capacity record for HC-PBGFs. These results are an important step towards ultralow-loss transmission fibers and illustrate the intriguing possibility to employ MDM in such low nonlinearity, low latency fibers.
