Pavement Analysis Part III: Rayleigh Waves in Layered Media

W.H. Coghill

ISVR Technical Memorandum 850

November 1999
**Technical Reports** are published to promote timely dissemination of research results by ISVR personnel. This medium permits more detailed presentation than is usually acceptable for scientific journals. Responsibility for both the content and any opinions expressed rests entirely with the author(s).

**Technical Memoranda** are produced to enable the early or preliminary release of information by ISVR personnel where such release is deemed to the appropriate. Information contained in these memoranda may be incomplete, or form part of a continuing programme; this should be borne in mind when using or quoting from these documents.

**Contract Reports** are produced to record the results of scientific work carried out for sponsors, under contract. The ISVR treats these reports as confidential to sponsors and does not make them available for general circulation. Individual sponsors may, however, authorize subsequent release of the material.

**COPYRIGHT NOTICE**

Chapter 1

Experimental Results

This chapter includes some experimental results and their possible interpretation.

1.1 Rayleigh waves on a table top

Accelerometers were placed on the surface of a table. The thickness of the surface of the table was 25mm. Waves of the Rayleigh type were generated in the surface of the table. The accelerometers were placed at a spacing of 32mm, in a radial line from the source of the waves. The difference in the phase of the wave arriving at the two accelerometers was measured. A phase difference of $2\pi$ radians corresponds with a wavelength of 32mm and a wavenumber, a reciprocal of the wavelength, of $1/0.032 = 31$ m$^{-1}$. The results are shown in Figure 1.1. This figure shows the time series measurement of the wave received at the two accelerometers. Samples were acquired at a rate of 11025 pairs of samples per second. The duration of the time series shown is approximately 3ms.

![Graph of voltage output vs sample number and phase difference vs frequency](image)

**Figure 1.1:** Rayleigh waves on the surface of a table.

The axis of the phase difference is $0.7\text{radians} / (2\pi) = 31$ m$^{-1}$ in length. Thus the group velocity between 2000Hz and 4000Hz is $2000/3.4 \approx 600$ m/s.
1.2 Route A6.

The phase velocity of waves of the Rayleigh type was measured on Route A6-Auxerre-Lyon, France [1]. The results of the measurements are shown in Figure 1.2. This figure shows the results of the measurements plotted in two ways. The first shows the phase velocity plotted against the wavelength in metres. The second shows the reciprocal of the wavelength plotted against the frequency in Hz.

The pavement consisted of a surface course 0.2m in thickness, overlying a gravel-cement basecourse 0.15m in thickness. The group velocities $\frac{\delta \omega}{\delta k}$ were read from the plot of the reciprocal of the wavelength against the frequency as shown in Table 1.1.

Table 1.1: LCPC Data: Estimated velocities within the structure.

Figure 1.2: Rayleigh waves on route A6-Auxerre-Lyon.

We attempt to match the data in Figure 1.2. We do this by searching for an ideal layered system which yields the same results as those shown in Figure 1.2. The results are shown in Figure 1.3. In Figure 1.3, the first sub-figure shows the phase velocity plotted against the wavelength. The second sub-figure shows the reciprocal of the wavelength plotted against the frequency. All quantities are in relative units. The velocity in the surface layer $\beta_1$ is unity, and the thickness of the surface layer is unity.

The theoretical match with the experimental results was obtained with the aid of the programme RAY.FOR (section A.4.2).

The programme RAY.FOR is used in order to calculate the expected response of a pavement surface to vibratory loading. The programme follows the mathematical expressions given by Thrower [12]. The data file for RAY.FOR is
RAY.DAT which is prepared with the aid of the programme PREP.FOR (section A.4.1).\(^1\)

The data file PREP.DAT used in the programme PREP.FOR was as follows.

```
LCPC DATA E1=11200,E2=34000,E3=1340;H1=0.1,H2=0.2,NU1=NU3=0.25,NU2=0.4
3 11200 .25 34000 .40 1340 .25 0.0
2 2 2
.10 .20
(3.5,.00) (.40,.00) (.10,.01) .02 .10
```

The parameters used in order to obtain the match were estimated as follows.

The measured values of the thicknesses of the layers were used as data. The values of Poisson's ratio were guessed as shown in the header line of the data. The densities in the three media were assumed to be equal. The velocities in each of the three media were estimated from the measured values of the reciprocal of the wavelength plotted against the frequency. The match is intended to be read by multiplying the calculated velocities and frequencies by one thousand. The corresponding values of the Young's moduli are as given in the header line of the data file, where the values shown are expressed in kPa.

Successive branches of the response can be computed by selecting suitable starting points for the programme RAY.FOR. This method was used to compute the multiple branches shown in Figure 1.3.

### 1.3 Hurn Airport

Data acquired from a taxiway at Hurn Airport, Dorset, England, were analysed. The aim was to

- Estimate the thickness of the surface layer
- Confirm the estimate by finding an ideal layered system which yields the observed measurements. This was done with the aid of the forward programme SON.FOR (section A.2).

The figure 1.4 shows the results of the measurements. The figure shows also the results of calculations made with the aid of the programme SON.FOR (section A.2). The measurements match a structure having a surface layer 0.64 metres in thickness.

\(^1\)The format of the datafile PREP.DAT is given in the appendix A.4.1
1.3.1 Procedure followed

The results shown in Figure 1.4 were obtained as follows. The inverse programme APP.S.FOR (section A.5.1), was used to estimate the thickness of the surface layer. Then the program SON.FOR (section A.2) was used to confirm the thickness of the surface layer, by performing forward calculations. The results of the forward calculations are shown in Figure 1.4. The results for three thicknesses are shown. The thicknesses are 320mm, 640mm and 1280mm.

1.3.2 The inverse programme APP.S.FOR

The inverse programme is based on the solution by Lee for the structure consisting of a surface layer overlying a semi-infinite medium. Lee’s solution is represented by a $2 \times 2$ determinant, in which the transcendental functions are approximated by their first terms only. The limiting velocities are read from the results of the experimental measurements. The velocities are supplied as data to the inverse program. The programme also requires values of the reciprocal wavelength and the frequency, which indicate the curvature of the plot of the reciprocal of the wavelength against the frequency. This final pair of data is subjective, and is inevitably a source of error. The inverse programme APP.S.FOR (section A.5.1) involves a first-order approximation to the frequency equation.

![Figure 1.4: Hurn Airport taxiway](image)

The theoretical match in Figure 1.4 was obtained with the aid of the programme APP.S.FOR. The estimate of the thickness of the surface layer was improved with the aid of the programme SON.FOR. The thickness of the surface layer could be measured independently by excavation or by interpreting the measurements of surface deflections in the neighbourhood of a known load.

1.4 Newbury runway

Measurements were performed on a disused airfield runway at Greenham Common, Newbury, Berkshire. The runway had been used by heavy aircraft, and

</tr>
</tbody>
</table>

Table 1.2: Greenham Common Pavement: Structural section.

showed extensive cracking. The results of the measurements are shown in Figure 1.5. This figure shows the reciprocal of the wavelength plotted against the frequency. The spacing between the accelerometers was 0.148m.

At frequencies below 10Hz, the phase velocity is approximately 2.5 metres per second. At frequencies from 20Hz to 60Hz, the group velocity is approximately 20 metres per second. These velocities are consistent with motion being transmitted between the loose particles of which the pavement is composed. The shape of the plot of the results suggests that the material in the surface layer is stiffer than that in the underlying medium. At frequencies between 80Hz and 115Hz, the group velocity is \( \frac{115 - 80}{11 - 9} \) or approximately 18 metres per second.

The programme APP.H.FOR (section A.5.2) yields a value of the thickness of 0.002m. The input data were as follows: \( \beta_1 = 20, \beta_2 = 2.5 \) Reciprocal wavelength 3.5, frequency 18. The estimate of the thickness of the surface layer is clearly incorrect.

The structure of the pavement was as shown in Table 1.2.

The velocity of waves of the Rayleigh type in concrete is normally 1000m/s or higher. The observed velocity is too low to correspond with a velocity in concrete. The low velocity is due to the cracks in the surface.\(^3\)

\(^3\)The dimensions of this fraction are Hz/m\(^{-1}\)
1.5 Airport pavement

Measurements of the phase velocity of waves of the Rayleigh type were performed on an airport runway pavement. The pavement was at HMS Daedalus, Solent, Hampshire, England. The results are shown in Figure 1.7. This figure shows the calculated value of the reciprocal of the wavelength plotted against the frequency.

The group velocities were read from Figure 1.7 as shown in Table 1.4:

The group velocities increase as the frequency increases. The lowest group velocity corresponds with the lowest frequency and with the lowest value of the reciprocal wavelength. This velocity represents the properties of the underlying medium. The highest group velocity corresponds with the properties of the

The programme APP.H.FOR (section A.5.2) yields the results shown in Table 1.5.

The estimated thicknesses are too small by a factor of ten.

### 1.6 Parking area

Measurements were performed at a parking area at 50, University Road, Southampton, England. The results are shown in Figure 1.8. This figure shows the reciprocal wavelength plotted against the frequency.

![Figure 1.8: Parking area. 1998](image)

The structure of the pavement was as shown in Table 1.6.

Table 1.7: Parking area: Numerical results of field measurements.

The group velocities were read from Figure 1.8 as shown in Table 1.8

Table 1.9 shows the estimated thickness of the surface layer obtained with the aid of the programme APP_H.FOR(section A.5.2).

1.7 Conclusions

It appears that the approximate inverse programs APP_H.FOR and APP_S.FOR yield useful results only when the contrast between the surface and underlying media is great. Examples are of an airport runway or freeway pavement. See Figure 1.4 and Figure B.1. This may indicate that an approximation of a higher order than the first is required.

The experimental results (Figures B.1 to B.8) indicate that the model developed corresponds with only very simple structures. It appears that additional parameters are required to represent more closely the results obtained from common structures.

Table 1.9: Parking area: Estimated thickness of surface layer using APP.H.FOR

The program SIN13.FOR (Section A.3) yields output corresponding to a solution of the equation described previously [4]. However the output does not correspond with a true zero of this equation. Instead the output corresponds with a value of the determinant which is small compared with the initial trial value. However the output obtained agrees with that obtained by means of the program RAY.FOR (Section A.4.2), for which the solution criterion is more rigorous.
Chapter 2

Computations

The programmes SON.FOR (section A.2), SIN13.FOR (section A.3) and RAY.FOR (section A.4.2) have been written in order to calculate the expected response of a layered system to the passage of waves of the Rayleigh type. SON.FOR and SIN13.FOR are intended for a system composed of a single layer overlying a semi-infinite medium; RAY.FOR is intended for a similar system but having more than one layer.

SON.FOR and SIN13.FOR were written in such a manner that all data and output are non-dimensional; RAY.FOR is written to permit some dimensionality to be incorporated.

SON.FOR is written for a system in which the propagation velocities increase with the depth below the surface. SIN13.FOR is intended for the system in which the velocities decrease with the depth below the surface. In RAY.FOR, the component media may be interspersed in any order of stiffness.

The solutions provided by the programmes SON.FOR, SIN13.FOR and RAY.FOR are non-unique. This is true particularly of SON.FOR and of RAY.FOR, which utilize periodic functions in developing the frequency equation. The solution corresponding with the lowest frequency is selected. This solution represents the most probable response of a real structure.

2.1 Scaling

The programmes SON.FOR and SIN13.FOR utilize non-dimensional quantities for both input and output. The results require scaling in order to match the computations with the measurements made on real structures.

The unit of length in SON.FOR and SIN13.FOR is $h$, the thickness of the layer.

2.1.1 Data Input

The data input to both of the programmes is as follows:

(a) $V$, the dimensionless trial wavelength. It is measured in units of $h/\pi$.

(b) $CB1$, the dimensionless velocity. It is measured in units of $\beta_1$.

$$V = \frac{\lambda}{\pi h}, \quad CB1 = \frac{c}{\beta_1}$$
The calculated dimensionless frequency is therefore

\[
\frac{CB1}{V} = \frac{c}{\beta_1} \frac{\pi h}{\lambda}
\]

and the dimensionless reciprocal wavelength is \( \frac{1}{V} = \frac{\pi h}{\lambda} \)

2.1.1.1 Ratio of densities

Densities do not vary significantly within a normal earthen structure, in comparison with the variation of the velocities of propagation of sound waves.

The ratio of densities \( \frac{\rho_2}{\rho_1} = \frac{\beta_2^2}{\beta_1^2} \frac{\mu_2}{\mu_1} \)

i.e. the density is directly proportional to the Lamé shear constant \( \mu \), and inversely proportional to the square of the velocity of shear waves \( \beta \) in the material.

2.1.1.2 Example, from 240a2.wk4

Measurements were performed on the surface of a parking area.\(^1\) The results of the measurements are shown in Figure 2.1. This figure shows the reciprocal of the wavelength plotted against the frequency.

![Figure 2.1: Results for analysis obtained from 240a2](image)

\[
\beta_1 = 2000m/s, \beta_2 = 300m/s, h = 0.255m.
\]

Unit frequency is

\[
\frac{c}{\lambda} = \frac{\beta_1}{\pi h} = \frac{2000}{0.255\pi} = 2,496Hz.
\]

Unit reciprocal wavelength is

\[
\frac{1}{\lambda} = \frac{1}{\pi h} = \frac{1}{0.255\pi} = 1.248m^{-1}
\]

\(^1\)At 50, University Road, The University, Highfield, Southampton, England.
2.1.2 Matching results

We thus obtain a procedure for matching experimental results.

2.1.2.1 Plot the experimental points as wavelength versus velocity;

2.1.2.2 Estimate the ratio of the greatest to the smallest velocities;

2.1.2.3 Write the data for SIN13.FOR (see section A.3) using the ratio of the greatest to the smallest velocities; estimate $\frac{\mu_2}{\mu_1}$ as the reciprocal square of the velocity ratio;

2.1.2.4 Run and plot SIN13.FOR;

The programme SIN13.FOR is an approximation only.

2.1.2.5 Prepare data for RAY.FOR, using PREP.FOR (see section A.4.1). Supply moduli in relative values only, based on the square of the ratio of the maximum to minimum velocities;

2.1.2.6 Run and plot PREP.FOR and RAY.FOR;

2.1.2.7 Go to section 2.1.2.3.

2.1.3 Example of matching experimental results

Figure 2.2 shows the results from Figure 2.1 plotted in an alternative manner. The phase velocity is plotted against the wavelength. The experimental points are denoted by Series1. The purpose of this is to facilitate matching this set of measurements with those expected from an ideal structure. The calculated results obtained from SIN13.FOR and from RAY.FOR are shown as Series2 and Series3 respectively. The behaviour of the structure does not correspond with that expected from an ideal structure. The match gives an indication of the properties of the associated ideal structure.

The following data file was used as input to PREP.FOR to obtain the indicated output from RAY.FOR.

| 240A2. Data for PREP.DAT |
| 2 10000. .25 100. .25 0.0 |
| 2. 2. |
| 0.6 |
| (5., .00) (.3, .00) (.01, .01) .0001 .05 |

2.1.3.1 Scaling the outputs obtained from SIN13.FOR and RAY.FOR

The dimensionless velocity obtained from SIN13.FOR was multiplied by 1000, and the dimensionless wavelength was divided by 600.

The dimensionless velocity obtained from RAY.FOR was multiplied by 1000. The output wavelength was divided by 7.0 indicating that the surface layer is 0.6/7.0 = 0.08m in thickness. The structure of the pavement is given in Table 1.6.

2.2 SON.FOR

The programme SON.FOR is written in order to calculate the expected response of a single-layered system to the passage of waves of the Rayleigh type. The system considered is that of a compliant layer overlying a stiff semi-infinite medium [2]. This system is the normal progression which occurs in nature. The programme is written in Fortran. It compiles with the aid of Microsoft Fortran Version 5.1.

2.3 SIN13.FOR

The programme SIN13.FOR is written in order to calculate the expected response of a single-layered system to the passage of waves of the Rayleigh type. The system considered is that of a stiff layer overlying a compliant semi-infinite medium. The programme is written in Fortran. It compiles with the aid of Microsoft Fortran Version 5.1.
(1) Title;
(2) Number of media in the structure, Young's modulus and Poisson's ratio of each, Write Switch (0.0=essential output only: 1.0=all information);
(3) Densities of the materials in each medium;
(4) Thicknesses of layers in the structure;
(5) Initial wavelength, Trial velocity, Increment of trial velocity, Ratio of final to initial wavelength, wavenumber step at which calculations are to be made.

Table 2.1: Form of the data input to PREP.DAT

It is written according to Lee's determinant for a system composed of a stiff layer overlying a semi-infinite medium composed of a material having a lower stiffness than the material in the layer [3].

2.4 RAY.FOR

The programme RAY.FOR was written in order to calculate the expected response of a layered system to the passage of waves of the Rayleigh type. The programme is written in Fortran. It compiles with the aid of Microsoft Fortran Version 5.1. The programme PREP.FOR was written in order to prepare a datafile for input to RAY.FOR. The input to PREP.DAT is in free format. As an example, the following data were used in an attempt to obtain Figure 1.3. The input to PREP.DAT requires the data described in Table 2.1.

The contents of PREP.DAT used in order to match the data in Figure 1.2 were as follows:

```
DATA E1=11200,E2=34000,E3=1340,H1=0.1,H2=0.2,NU1=NU3=0.25,NU2=0.4
3 11200. .25 34000. .40 1340. .25 0.0
2. 2. 2.
.10 .20
(3.5, .00) (.40, .00) (.10, .01) .02 .10
```

All calculations in RAY.FOR are made with reference to the velocity $\beta_1$, the velocity of shear waves in the surface layer. The value of $\beta_1$ is treated as unity in the calculations.

However the true layer thicknesses, as supplied in the data PREP.DAT, were used. This was done in order to avoid complications caused by the exponential decay of displacements with the depth in each layer. These complications could be overcome: see the subroutine EMATRX. This subroutine would require rewriting if the thickness of the surface layer were fixed as unity.

The output from RAY.FOR, therefore requires scaling in order to match any real system. The operation of scaling would be more simple if the thickness of the surface layer, in addition to the velocity of shear waves, were treated as unity.

The calculated response is scaled in order to match the results of the observed field measurements. The scale factor is then used to determine the true properties of the media of which the structure is composed. As an example, the
calculated results of the structure need to be multiplied by a factor of one thousand in order to match the results of the field measurements. This translates to multiplying the elastic moduli by $10^6$, showing that the moduli used in the data are in megapascals. The resulting values fall within the expected ranges of the moduli.
Bibliography

Appendix A

Program listings

A.1 Introduction

This appendix contains listings of the programmes used in the computations. Sample data are enclosed for each program, except for the two interactive programmes APP.S.FOR and APP.H.FOR.

A.2 SON.FOR

The program SON.FOR was written in order to match experimental results obtained from a system consisting of a layer of compliant material overlying a semi-infinite medium. The material within the semi-infinite medium is less compliant than that in the overlying layer.

A listing of the source program follows, accompanied by a set of sample data.

A.2.2 Sample output from program SON.FOR
Abbreviated sample output is shown in Table A.1 for the program SON.FOR

A.3 SIN13.FOR
The program SIN13.FOR was written in order to match experimental results obtained from a system consisting of a layer of stiff material overlying a semi-infinite medium. The material within the semi-infinite medium is less stiff than that in the overlying layer.

A listing of the source program follows, accompanied by a set of sample data. The program is an approximation only. The result is obtained not as true zero of the determinant of the frequency equation. Instead it is obtained when the value of the determinant is a small fraction of its initial trial value.

Table A.2: Sample output from program SIN13.FOR

to five media, consisting of four layers overlying a semi-infinite medium. The
stiffnesses of the materials within the system may be in any order.
The data is prepared by means of a program PREP.FOR.

A.4.1 PREP.FOR

The program PREP.FOR is written in order to prepare the data file RAY.DAT
required for the program RAY.FOR. A listing of the program PREP.FOR follows.

PROGRAM PREP
C THIS PROGRAM PREPARES DATA FOR RAY. THE INPUT IS IN FILE PREP.DAT
C THE DATA LINES IN PREP.DAT ARE TITLED,
C NS,(EM(I),V(I), I=1,NS),SWITCH
C (RHO(I),I=1,NS)
C (HH(I),I=1,N)
C WLNTH,CD1TRA,CINCR ALLCOMPLEX, WLFAC,DLFAC BOTH REAL
C
DIMENSION EM(5),V(5),RHO(5),HH(5),TITLE(20)
COMPLEX WLNTH,CD1TRL,CINCR
C OPEN FILE PREP.DAT WHICH CONTAINS DATA IN FREE FORMAT.
OPEN(1,FILE='PREP.DAT',STATUS='OLD')

C OPEN FILE RAY.DAT TO ACCEPT DATA IN FIXED FORMAT.
OPEN(3,FILE='RAY.DAT',STATUS='UNKNOWN')
REWIND 3

END

The contents of PREP.DAT are as follows:

| (1) Title; |
| (2) Number of media in the structure, Young’s modulus and Poisson’s ratio of each, Write Switch(0.0=essential output only: 1.0=all information); |
| (3) Densities of the materials in each medium; |
| (4) Thicknesses of layers in the structure; |
| (5) Initial wavelength, Trial velocity, Increment of trial velocity, Ratio of final to initial wavelength, wavenumber step at which calculations are to be made. |

The input to the program PREP.FOR is as follows.

```
LCPC DATA E1=11200,E2=34000,E3=1340;H1=0.1,H2=0.2,NU1=NU3=0.25,NU2=0.4
3 11200. .25 34000. .40 1340. .25 0.0
2. 2. 2.
.10 .20
(3.5, .00) (.40, .00) (.10, .01) .02 .10
```

### A.4.2 RAY.FOR

The program PREP.FOR outputs a data file labelled RAY.DAT. This file is read as input to the program RAY.FOR.

A listing of the program RAY.FOR follows. The data is supplied by the output from PREP.FOR. The output from RAY.FOR is the file RAY.PRN.
file RAY.PRN shows the phase velocities, the wavelengths, the wavenumbers
and the frequencies for each point which is calculated.

Table A.3: Sample output from program RAY.FOR
A.5 Inverse programmes APP_S.FOR and APP_H.FOR

Inverse programmes APP_S.FOR and APP_H.FOR were written in order to facilitate matching results of measurements with those expected from ideal layered structures. The ideal structures are composed of a single layer overlying a semi-infinite medium. The program APP_S.FOR is intended for a structure in which the stiffness of the materials increases with the depth. The program APP_H.FOR is for the opposite case, in which the stiffness of the materials decreases with the depth.

Both programmes are intended to be used interactively. The limiting velocities $\beta_1$ and $\beta_2$ are supplied at a prompt from the program. Then a point on the plot of reciprocal wavelength versus frequency is entered in response to a prompt. The point is selected, subjectively, to indicate the curvature of the plotted experimental points.

Both programmes utilize an approximation to the frequency equation of the system. The approximation is based on expanding the transcendental functions to their first terms. While not consistently so, it appears that these programmes yield thicknesses of the surface layer which are too small by a factor of two. This error could possibly be decreased if additional terms were used in the approximation.

A.5.1 APP_S.FOR

c This is an inverse program. The limiting velocities are read. Then
c pairs of reciprocal wavelength and frequency are used interactively to
c calculate the thickness of the surface layer. The calculation is the
c result of a quadratic: two values of the thickness are obtained.
c
This program is an approximation to Lee’s determinant for the
c “soft over hard” case, using a first order expansion of the transcendental
c functions. It is based on equation (21) in the condensed version of
c A.W.Lee’s paper, A.W.LEE.DOC. The full paper is A.W.Lee, “The effect of
c geological structure upon microseismic disturbance“, Monthly Notices of the 10
c Royal Astronomical Society, Geophysical Supplement, Vol 3, 1932,
c pp. 83 - 105. It solves for $<h>$ in terms of the

c measured quantities, $c$ the reciprocal wavelength and the corresponding
c frequency. The coefficients “aa”, “bb”, “cc” are derived in the
c Mathematica notebook LEE_EQS.nb, where they are expressed in Fortran

c form using LEE_EQS.nb

A.5.2 APP_H.FOR

c The following file is an approximation to Lee's determinant for the
c "hard over soft" case, using a first order expansion of the transcendental
c functions. It is based on equation (81) in the condensed version of
c A.W.Lee's paper, A.W.LEE.DOC. It solves for \( \chi \) in terms of the
c measured quantities, the reciprocal wavelength and the corresponding
c frequency. The coefficients "aa", "bb", "cc" are derived in the
c Mathematica notebook LEE/APP_H.MA, where they are expressed in Fortran
c form.

Appendix B

Errors in inverse

In this appendix a further evaluation is attempted of the approximate inverse programme APP.H.FOR (section A.5.2). Interpretations made with the aid of APP.H.FOR are given, followed by graphical presentation of the experimental results.

B.1 Experimental results.

Table B.1 and Table B.2 have been given previously. They are presented again for convenience, followed by graphs of the experimental results. The graphs show also the approximations made and referred to in Table B.1 and Table B.2. The equation quoted by Cogill [3] is used with the results given in Cogill [2] to obtain a quadratic equation in terms of the pavement thickness h.

By extrapolating the data shown in Fig. B.1: \( \alpha_1 = 1732\text{m/s}, \beta_1 = 1000\text{m/s}, \alpha_2 = 346\text{m/s}, \beta_2 = 200\text{m/s} \). At reciprocal wavelength = 1.0, the frequency is 470Hz. The approximation leads to a calculated thickness of 0.19m. The measured overall thickness of the surface slab is 0.22m. The results are shown in Table B.1.

The system analysed next consisted of 150 mm compacted thickness of limestone quarry scalplings, and a surface course of 60 mm consolidated thickness of

Table B.2: Approximate layer thicknesses, calculated from the results of the measurements of the surface phase velocity at various frequencies: Prepared base course 0.15m in thickness.

28 mm nominal size dense limestone bitumen macadam base course and 25 mm compacted thickness of 10 mm nominal size dense limestone bitumen macadam wearing course. From results of measurements made on this system, (COMBA2) $\alpha_1 = 2771 m/s$, $\beta_1 = 1600 m/s$, $\alpha_2 = 866 m/s$, $\beta_2 = 500 m/s$. At a value of the reciprocal wavelength = 1.0, the frequency is 900 Hz. The approximation leads to a calculated thickness of 0.10m.

Finally, field measurements were performed on the surface of a base course composed of unbound gravel laid on a prepared subgrade. Table B.2 shows the values of the approximate thicknesses calculated from the results obtained$^3$. The approximation is valid only at low frequencies, although complete measurements must be performed in order to estimate the limiting velocities of propagation in the media composing the structure.

The following figures show the results of experimental measurements on pavements having a variety of compositions. The approximations, indicated in Tables B.1 and B.2, are shown in the figures.

### B.2 Constructed pavements

The results shown in Figures B.1 to B.4 were obtained on the surfaces of constructed pavements. The results of the interpretations are summarized in Table B.1.

### B.3 Prepared basecourses

The results shown in Figures B.5 to B.8 were obtained on the surfaces of prepared basecourses. The results of the interpretations are summarized in Table B.2.
