Review

- L1 feature combinations influenced initial L2 mapping (Feature Reassembly H.);
- L2 learners successfully reassembled features into L2 bundles (off-line task);
- L1 representations might have a longer-lasting impact on language processing;
- L2 learners' reactions to the mismatching input delayed compared to natives.

Re-assembling Objects: a New Look at the L2 Acquisition of Pronominal Clitics

Abstract

We test the predictions of the Feature Reassembly Hypothesis (FRH) as applied to the L2 acquisition of French pronominal clitics by Anglophone learners, capitalizing on the fact that different semantic and morphosyntactic features are lexically encoded by French and English pronouns. A picture selection task and a self-paced reading task examine how the information encoded in the L2 forms affects off-line and on-line pronoun interpretation. Our findings suggest that the initial L1–L2 mapping was indeed influenced by the L1. Nevertheless, L2 learners successfully reassembled features into L2 bundles, as evidenced by target-like off-line performance. L2 reading time patterns, however, indicate that L1 representations may have a longer-lasting impact: learners' reactions to the mismatching input followed a different pattern and were slightly delayed as compared to native speakers'. These results are in line with the FRH, which conceptualizes L1 influence as the transfer of atomic linguistic features and their combinations.

Introduction

One of the most obvious and often cited explanations for the difference between invariably successful first language (L1) acquisition and the variable results of second language acquisition (L2) is the fact that L2 learners have already mastered one language. Few L2 researchers (or L2 speakers) would probably deny that L1 grammar is the source of some of the errors observed in an L2. But what exactly is transferred from the L1 into the grammar of subsequently acquired languages? Providing a straightforward answer to this question remains the topic of numerous studies in the field of L2 acquisition. A recently proposed account, the Feature Reassembly

1
2
3 Hypothesis (Lardiere, 2009) (FRH), suggests that L2 learners initially transfer the lexical
4
5 encoding of the L1 morphosyntactic and semantic features.
6
7

8 Following in the steps of the Full Transfer Full Access hypothesis (FTFA, Schwartz &
9
10 Sprouse, 1994, 1996), the FRH assumes that adult learners bring a system of formal features,
11
12 already assembled into native lexical items, to the L2 acquisition task. This view relies on the
13
14 assumption that syntactic features are morphosyntactic primitives (Chomsky, 1995) and that the
15
16 lexicon of these features determines the “parametric profile” of a particular language (Borer,
17
18 1984). Cross-linguistic variation is understood as differences in which features are lexically
19
20 encoded and how they are “bundled” into lexical items (Giorgi & Pianesi, 1997). The FRH
21
22 refines the FTFA proposal by insisting that successful L2 acquisition ultimately depends on
23
24 reconfiguring the feature bundles of L1 lexical items into those of the L2, in cases where
25
26 differences exist. If linguistic features are assumed to be reflections of universal cognitive
27
28 categories, we can assume that “new” features, not encoded in L1, will be acquirable in the L2 as
29
30 long as they are detectable in the input. At the outset of interlanguage development, however,
31
32 specific L1 feature combinations are associated with what are perceived as their closest L2
33
34 lexical equivalents. This phase is known as the MAPPING stage. As learners get more exposure to
35
36 the L2, it becomes possible to add new features not instantiated in their L1, eschew L1 features
37
38 not encoded in the L2 and reassemble native features that do not coincide within the same lexical
39
40 items in the L2, during the REASSEMBLY stage.
41
42
43
44
45
46
47

48 Most of the studies testing the FRH have addressed the question of featural
49
50 representations and their effect on L2 comprehension off-line. For instance, the hypothesis has
51
52 been applied to the study of L2 acquisition of number in L2 English and L2 Korean (Lardiere,
53
54 2009; Hwang & Lardiere, 2013), of existential quantifiers in L2 Korean, Chinese and English
55
56
57
58
59
60

1
2
3 (Gil & Marsden, 2013), and of expressions of definiteness and specificity in L2 Russian (Cho &
4
5 Slabakova, 2014). The existing studies have largely confirmed the predictions of the hypothesis
6
7 with respect to L1 transfer at the initial stages of L2 acquisition, i.e. the MAPPING stage. For
8
9 instance, beginning L2 learners of Mandarin Chinese and Korean (L1s English & Japanese) map
10
11 L2 *wh*-expressions solely to interrogatives, as in their L1s, and do not show evidence of
12
13 interpreting L2 *wh*-expressions as *wh*-existentials, a possibility available in the L2 (Gil &
14
15 Marsden, 2013).
16
17
18
19

20 The present cross-sectional study pursued two main goals. First, we set out to test the
21
22 predictions of the FRH beyond the initial MAPPING stage. We focused on the acquisition of
23
24 French object pronouns by native speakers of English since pronominal paradigms in English
25
26 and French lexically encode a different set of features. Our goal was not only to establish the
27
28 initial mappings but also to understand how L1 bundles are gradually reassembled to match L2
29
30 features. To achieve this goal, we investigated how cross-linguistic differences in features
31
32 encoded by pronouns affect learners' interpretations of L2 (French) object clitics (*le* and *la*) at
33
34 different proficiency stages.
35
36
37
38

39 Second, we sought to explore how L1-L2 (mis)matches in lexical encoding of formal
40
41 features affect on-line language processing, thereby extending the application of the FRH beyond
42
43 the acquisition of grammatical representations. L1 transfer has been proposed as one of the
44
45 explanations contributing to the differences observed between L1 and L2 processing profiles
46
47 (Clahsen & Felser, 2006; Hopp, 2010). The research available today seems to converge on the
48
49 idea that at the representational level advanced L2 learners can ultimately reassemble features
50
51 from their original L1 bundles (Choi & Lardiere, 2006; Cho & Slabakova, 2014). What remains
52
53 to be seen is whether L2 processing routines are automatically adjusted to process lexical items
54
55
56
57
58
59
60

1
2
3 available in L2 once the corresponding feature bundles have been established in the grammar.
4
5 Assuming L1 featural representations are eventually reassembled into new L2 bundles, does
6
7 completion of this reassembly process automatically alter L1 processing routines? Or does it take
8
9 L2 learners additional time to adjust on-line computations based on the new L2 representations?
10
11
12
13

14 15 **French and English object pronouns** 16

17 In spite of the close typological relationship between English and French, the pronominal
18
19 paradigms differ in some important respects. First, French, unlike English, has both strong and
20
21 weak/clitic object pronouns in its paradigm (Riemsdijk, 1999; Zwicky, 1977). Acquisition of
22
23 clitic object pronouns has been extensively studied in Romance languages (mainly Spanish and
24
25 French). It is now well established that different populations of learners experience difficulties
26
27 with this grammatical category, namely normally developing monolingual and bilingual children,
28
29 children with SLI, adult L2 learners and heritage speakers (Bruhn-Garavito & Montrul, 1996;
30
31 Duffield, White, Bruhn de Garavito, Montrul & Prévost, 2002; Grüter, 2005; Jakubowicz, Nash,
32
33 Rigaut & Gérard, 1998; Montrul, 2010; Paradis, Crago, Genesee & Rice, 2003; White, 1996;
34
35 Zesiger, Zesiger, Arabatzi, Baranzini, Cronel-Ohayon, Franck, Frauenfelder, Hamann & Rizzi,
36
37 2010). This difficulty has been attributed to phonological properties of clitic pronouns, their non-
38
39 canonical merging site, their special functional category status, or the complex nature of the
40
41 clitic-argument dependency. Most of the L2 studies focused on object clitic production (French:
42
43 Adiv, 1984; Granfeld & Schlyter, 2004; Hawkins, 2001; Herschensohn, 2004; Schlyter, 1997;
44
45 Selinker, Swain & Dumas, 1975; Towell & Hawkins, 1994; Véronique, 1989; Spanish: Liceras,
46
47 1985; Liceras, Maxwell, Laguardia, Fernández, Fernández & Díaz, 1997; Montrul, 2010) and on
48
49 testing the knowledge of clitic placement (French: Bruhn-Garavito & Montrul, 1996; Duffield et
50
51
52
53
54
55
56
57
58
59
60

1
2
3 al., 2002; Hoover & Dwivedi, 1998; Spanish: Duffield et al., 2002; Duffield & White, 1999;
4
5 Montrul, 2010). This research demonstrates that in spite of initial difficulties associated with the
6
7 non-canonical position of object clitics in Romance, L2 learners are able to master rules of clitic
8
9 placement, even if their L1 does not have pronominal clitics (Duffield & White, 1999; Montrul,
10
11 2010).
12
13

14
15 Building on these studies, we aimed at exploring how L1-L2 featural (mis)matches affect
16
17 pronoun comprehension and on-line processing.¹ In spite of their special syntactic status, French
18
19 pronominal clitics are referential pronouns (as opposed to anaphors and R-expressions) and
20
21 function similarly to English object pronouns in terms of establishing referential relations with
22
23 antecedents in the preceding discourse. In production, the choice between a pronoun and an R-
24
25 expression could depend on several factors, such as discourse structure (e.g. topic/focus
26
27 distinction), syntactic function (e.g. subject/object distinction), linear distance between the
28
29 antecedent and the pronoun as argued by Accessibility Theory (Ariel, 1990, 1994). In
30
31 comprehension resolving a clitic pronoun reference, just like resolving any pronoun reference,
32
33 relies on feature matching as well as on the knowledge of binding syntactic restrictions
34
35 (Chomsky, 1981) and discourse principles. The evidence available today suggests that both types
36
37 of information (grammatical and discourse information) are utilized in on-line resolution of
38
39 pronouns (Grodzinsky & Reinhart, 1993). For example, Arnold, Eisenband, Brown-Schmidt and
40
41 Trueswell (2000) found that native speakers of English simultaneously access (natural) gender
42
43 information and linear distance/order of mentioning information in resolving English subject
44
45 pronouns. Rigalleau, Caplan and Baudiffier (2004) further confirmed that native speakers of
46
47 French are sensitive to (natural) gender disagreement when processing pronouns that refer to a
48
49 discourse focus.

Extending our comparison of French and English pronouns beyond the presence/absence of clitics, we will now focus on lexically encoded feature combinations essential for feature matching operation during pronoun resolution. Both languages lexically encode a three-way person distinction: first person (English: *me/us*, French: *me/nous*), second person (English: *you*, French: *te/vous*) and third person (English: *him/her/it/them*, French: *le/la/lui/les/leur*).² As is clear from these examples, both languages also encode number in a similar way.

While both English and French third person forms encode person and number features, they encode natural and grammatical gender information differently. French has GRAMMATICAL gender, which means that its nouns are grouped into “noun classes” (feminine and masculine) based on “formal assignment rules” (Corbett, 1991). Moreover, elements that syntactically depend on a noun (adjectives, determiners, participles) carry either masculine or feminine morphological agreement markers. Just like nouns and their dependent elements, French clitic object pronouns *le* and *la*, the focus of the current study, also encode the masculine and feminine gender of their antecedents. In the case of accusative clitics, French does not make any lexical distinctions between [\pm Human] referents, which forces us to conclude that French does not lexically encode the [\pm Human] feature.

English differs from French in two respects. First, English uses different pronominal forms to refer to [$+$ Human] and [$-$ Human] referents (*him* or *her* vs. *it*). Second, English categorizes some nouns as masculine and feminine based on their meaning (NATURAL gender): male humans are classified as masculine (e.g. *him*), females as feminine (e.g. *her*) and all other nouns as neuter (e.g. *it*). Furthermore, English has a “pronominal gender system” (Corbett, 1991, p. 12), meaning that natural gender of an antecedent is lexically encoded only by personal, possessive and reflexive pronouns. English adjectives, determiners, and participles are not

morphologically marked for gender.

<Insert Figure 1 about here>

Figure 1 visually presents the similarities and the differences in feature specifications of (accusative) object pronouns in English and French. To summarize the differences crucial for the present study, English object pronouns lexically encode the [\pm Human] feature and NATURAL gender of their referents, while French accusative clitics lexically encode GRAMMATICAL gender but do not lexically encode the [\pm Human] feature. These cross-linguistic differences in lexically encoded feature bundles can be problematic for L2 pronoun resolution. To give readers an example of potential difficulties, let us consider the mini-dialogue in (1) and the possible interpretations of the object pronoun in the last sentence (*it/la*).

(1) *A : Je n'aime pas quand mon frère entre dans mon bureau. Il range mes bouquins et mes papiers et après je ne peux plus rien trouver! Hier il a passé 5 minutes dans mon bureau et aujourd'hui je ne trouve ni mon dictionnaire, ni ma rédaction pour la classe d'espagnol.*

*B : Mais non! C'est pas de sa faute! Tu **la** cherches déjà depuis trois jours!*³

A: I don't like it when my brother enters my home office. He rearranges my books and my papers and then I cannot find anything anymore! Yesterday he spent 5 minutes in my home office and today I can find neither my dictionary, nor my composition for the Spanish class!

*B: No! It's not his fault! You've been looking for **it** for three days already!*

The English sentence does not provide grammatical means to unambiguously identify the referent of the object pronoun *it*, since *it* could refer to either *the dictionary* or *the composition*.

A speaker might, of course, try to use discourse principles (e.g. recency of mentioning) to resolve the pronoun reference. Lexical encoding of gender in French allows unambiguous

1
2
3 pronoun resolution, since *la* can only refer to *the composition* (feminine noun in French) and not
4 to *the dictionary* (masculine noun in French). An L2 learner of French needs to realize that
5
6 French pronouns lexically encode grammatical gender, which means that, if necessary, gender
7
8 information can be used to identify not only human antecedents but also disambiguate between
9
10 inanimate antecedents, as demonstrated in (1). The goal of the current study was to test whether
11
12 L2 learners initially transfer feature specifications associated with L1 pronouns into their L2
13
14 grammar, hindering their accuracy of pronoun reference resolution, and whether subsequent
15
16 reassembly is possible to achieve target-like interpretations.
17
18
19
20
21
22
23
24

25 **Acquisition and on-line processing of gender**

26
27 Before we discuss relevant L2 research on gender processing, we would like to briefly review
28
29 some L1 findings in the domain of gender acquisition. It is important to establish how natural
30
31 and grammatical genders are acquired and processed by native speakers to be able to compare L1
32
33 and L2 patterns. Children acquiring languages with grammatical gender initially rely on
34
35 morphophonological (e.g. gender suffixes) and syntactic (e.g. gender agreement) cues to assign
36
37 gender to nouns rather than on extra-linguistic cues, such as natural gender of human referents
38
39 (Karmiloff-Smith, 1979; Pérez-Pereira, 1991). As for L1 processing of gender agreement, adult
40
41 speakers process it at a syntactic level (Friederici, 2002; Gunter, Friederici & Schriefers, 2000;
42
43 Hagoort & Brown, 1999; Sabourin, 2001) with gender congruent markers producing a robust
44
45 facilitation effect on language processing (Bates, Devescovi, Hernandez & Pizzamiglio, 1996;
46
47 Franceschina, 2005; Grosjean, Dommergues, Cornu & Guillelmon, 1994; Guillelmon &
48
49 Grosjean, 2001).
50
51
52
53
54

55 Research on L1 processing of agreement in general suggests that different morphological
56
57
58
59
60

1
2
3 features might have “different degrees of cognitive salience” (Carminati, 2005, p. 273, but see
4
5 Silva-Pereyra & Carreiras (2007) for an opposing view). French and English differ in their
6
7 criteria for gender assignment (formal gender assignment in French and semantic gender
8
9 assignment in English), which could possibly lead to different processing profiles for
10
11 grammatical and natural gender. Data from gender agreement errors (Spanish and French)
12
13 showed that sentential subjects that encoded natural gender triggered fewer gender agreement
14
15 errors on predicative adjectives than sentential subjects that encoded grammatical gender
16
17 (Vigliocco & Franck, 2001). These findings suggest that in language production, grammatical
18
19 gender might indeed have a different status than natural gender. However, these findings are not
20
21 necessarily directly applicable to the interpretation of pronouns. Indeed, in a series of three
22
23 experiments with native speakers of Spanish and French, Garnham, Oakhill, Ehrlich and
24
25 Carreiras (1995) found strong facilitation effects with both grammatical and natural gender of
26
27 object pronouns. The researchers analyzed clausal reading times, question-answering times and
28
29 question-answering accuracy and found facilitation effects in contexts where gender provided
30
31 cues for interpreting object pronouns that referred to inanimate things as well as those that
32
33 referred to people.
34
35
36
37
38
39

40
41 Compared to early and relatively error-free L1 acquisition of gender classification and
42
43 gender agreement, the end-result of L2 acquisition in this domain is much more variable. It has
44
45 been observed, for example, that L2 learners make more gender errors with certain grammatical
46
47 categories than others (e.g. more errors with adjectives than with determiners) (Liceras, Díaz &
48
49 Mongeon, 2000; Foucart & French-Mestre, 2011) and that native speakers of grammatical
50
51 gender languages achieve better results than those whose L1 does not have grammatical gender
52
53 (Foucart & French-Mestre, 2011; Franceschina, 2005; Sabourin, 2001; Sabourin & Stowe, 2008).
54
55
56
57
58
59
60

1
2
3
4 The existing research provides conflicting evidence with respect to ultimate acquirability
5
6 of gender agreement by L2 learners. Studies that tested off-line and on-line gender
7
8 comprehension found very accurate performance of L2 learners (Bruhn de Garavito & White,
9
10 2003; Foucart & Frenck-Mestre, 2011; Gabriele, Fiorentino & Alemán Bañón, 2013; Gillon
11
12 Dowens, Vergara, Barber & Carreiras, 2010; Grüter, Lew-Williams & Fernald, 2012; Montrul,
13
14 Foote & Perpiñán, 2008; Tokowicz & MacWhinney, 2005; White, Valenzuela, Kozłowska-
15
16 MacGregor & Leung, 2004). However, learners' difficulties in producing correct morphological
17
18 realizations of gender agreement are largely documented in the L2 literature (Franceschina,
19
20 2005; Grüter et al., 2012). These conflicting findings are suggestive of a possible divide between
21
22 a syntactic computation of gender agreement and lexical knowledge of gender. In other words, it
23
24 is possible that gender agreement becomes unproblematic once L2 learners are able to correctly
25
26 assign nouns to their target gender classes. For instance, Hopp (2013) found that those learners
27
28 of German who possessed stable lexical knowledge of gender were able to use it as a predictive
29
30 cue demonstrating that agreement mechanisms rely on lexical knowledge.
31
32
33
34
35

36
37 There is evidence to suggest that the distinction between natural and grammatical gender
38
39 affects L2 learners' performance. However, research on the impact of the semantic feature
40
41 [\pm Human] on on-line processing of gender agreement has so far produced contradictory results.
42
43 These differences in the experimental findings might be explained by the part of speech
44
45 participating in the agreement relationship, the specific language combination and experimental
46
47 design. In the domain of adjectival agreement, gender agreement violations triggered longer
48
49 reading times with animate nouns than with inanimate nouns in the data of monolingual and
50
51 intermediate-proficiency L2 speakers of Spanish (Sagarra & Herschensohn, 2010), leading the
52
53 researchers to conclude that "the processing of agreement with animate nouns is cognitively
54
55
56
57
58
59
60

1
2
3 more demanding than with inanimate nouns.” (p. 106). Contrary to these findings, Irmen and
4
5 Knoll (1999) found that for native speakers of German, gender cues facilitated processing of
6
7 pronouns that referred to people as well as objects. In the same experiment, gender cues
8
9 facilitated sentence interpretation only when pronouns referred to people for Finnish L2 learners
10
11 of German. Several considerations warrant further investigation of the impact of L1 encoding of
12
13 natural and grammatical gender on L2 development. First, gender agreement might affect
14
15 processing of different parts of speech differently, e.g. the difference between adjective-noun
16
17 gender agreement and antecedent’s gender encoded by a pronoun. Secondly, the language
18
19 combination studied by Irmen and Knoll (L1 Finnish–L2 German) is not optimal for
20
21 investigating the role of L1 feature transfer, since Finnish encodes neither grammatical, nor
22
23 natural gender in the pronominal paradigm. Finally, the experimental design of Irmen and Knoll
24
25 did not focus on incremental processing of gender, nor did it investigate how L2 knowledge of
26
27 gender develops across different proficiency levels.
28
29
30
31
32
33
34
35

36 **Motivation and research questions**

37
38 Deprived of proper lexical meaning, pronouns encode semantic and morphosyntactic features
39
40 that facilitate the task of establishing a referential link between pronouns and their discourse
41
42 antecedents or real-world referents. The features that contrast pronominal forms within the
43
44 paradigm are, however, language specific. While object pronouns in both French and English
45
46 encode person and number, the languages differ in lexical encoding of the semantic feature
47
48 [\pm Human] and the morphosyntactic feature of GRAMMATICAL gender. The differences between
49
50 the paradigms make any initial mappings highly problematic and potentially misleading.
51
52
53 Following the predictions of the FRH, we assume that L2 learners initially transfer lexically
54
55
56
57
58
59
60

1
2
3 encoded L1 feature bundles and map them to their closest L2 equivalents. In the case at hand
4
5 Anglophone learners of French will need to map three L1 forms onto the two forms available in
6
7 L2, as it is depicted in Figure 2 below:
8
9

10 <Insert Figure 2 about here>
11

12 In its current formulation, the FRH does not allow specific predictions with respect to the
13 mapping that L2 learners might attempt in a situation such as the one we are considering here.
14
15 However, it predicts that learners will initially map L1 feature bundles even if they do not
16
17 coincide with feature specifications of the L2 items. Thus, we can expect learners to be more
18
19 accurate when pronominal reference is determined by semantic gender than when it is
20
21 determined by grammatical gender. Alternatively, if L1 lexical encoding of features does not
22
23 affect L2 error patterns, we would expect learners to make interpretation errors with *le* and *la*
24
25 referring to people and non-humans to an equal or comparable degree.
26
27
28
29
30

31 The study was designed to answer three research questions about the two proposed stages
32
33 of feature reassembly.
34

35
36 During the initial mapping stage:
37

38
39 1) Do L2 learners interpret French object clitics more/less accurately depending on whether
40
41 they refer to people or to inanimate objects?
42

43
44 During the subsequent reassembly stage:
45

46
47 2) Do L2 learners of an L1 that lexically encodes only natural gender use grammatical gender
48
49 information to interpret L2 pronouns off-line?
50

51
52 3) Do L2 learners of an L1 that lexically encodes only natural gender use grammatical gender
53
54 information to interpret L2 pronouns on-line?
55
56
57
58
59
60

Method

Participants

A group of native speakers of French ($n = 43$) and a group of L2 learners of French (L1 English) ($n = 87$) participated in the experiment. Native speakers of French were tested in France and recruited among students at two major universities in Paris (Mean age = 21.6). All French native speakers reported some knowledge of English: 56% reported advanced and 42% intermediate proficiency in English. Thus the native speakers were essentially bilingual, which makes them comparable in this respect to our learner group. Second language learners of French were tested in the U.S. and were either enrolled in college-level French courses at a large Midwestern university or worked as French instructors at the same institution (Mean age = 21.7). All participants received financial compensation for their participation.

All participants completed a C-test assessing their proficiency in French (Renaud, 2010). The C-test consisted of two short texts, each containing 25 blanks. The first sentence of each text was left intact. In the remainder of the text every other word contained a blank. Participants were asked to fill in the second half of the words that contained blanks. Each correctly completed item was given a point; partially correct completions received the score of .5. Items left blank, meaning-incompatible answers or answers with more than 2 spelling errors were scored as 0. For more details on the format of the test and the scoring criteria the reader is referred to Renaud (2010). Based on the results of the C-test, we divided the L2 learners into three proficiency groups, see Table 1.

<Insert Table 1 about here>

Procedure

1
2
3 All participants were tested individually in a quiet environment on one of the university
4 campuses. The four experimental tasks and the background questionnaire were presented on a
5 computer in the following order: the self-paced reading task, the background questionnaire, the
6 grammaticality judgment task, the picture selection task, and the C-test. Here we present the
7 results of the self-paced reading and the picture selection tasks. Participants met with the
8 researcher, who was available during the testing session to answer clarification and/or
9 vocabulary questions about the experimental tasks. Participants completed all the tasks in one
10 session that usually lasted for an hour and a half (range from one hour to two hours) and were
11 allowed to take breaks as necessary.

27 **Materials**

28 *Picture selection task*

29
30
31 The French system of gender assignment is quite opaque, with some morphological and
32 phonological generalizations (Corbett, 1991). However, neither the picture selection task, nor the
33 self-paced reading task tested learners' lexical knowledge of gender. The picture selection task
34 was specifically designed to determine whether the type of antecedent available in the context
35 affected the accuracy of the participants' interpretations of French accusative clitics *le* and *la*.
36 Here we report the results of two experimental conditions of the picture selection task. Both
37 conditions tested the influence of gender on pronoun resolution of *le* and *la*. In the [+Human]
38 condition we tested the use of gender in contexts where *le* and *la* referred to a HUMAN, while in
39 the [-Human] condition we tested the use of gender in contexts where the clitics referred to an
40 INANIMATE object. The picture selection task contained 66 experimental items presented in a
41 pseudo-randomized order. Each test item consisted of:
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

- 1
2
3 (1) a short context introducing two potential referents (#1 & #2);
4
5 (2) the test sentence reintroducing one of these referents with a clitic (marked for gender);
6
7
8 (3) four types of responses presenting four referential possibilities:
9
10 a) referent #1,
11
12 b) referent #2,
13
14 c) both referents are possible,
15
16 d) a gender-matched distractor thematically compatible with the context, but not
17
18 mentioned previously.
19
20
21

22 All the contexts were presented in French. Each condition contained 6 items, each
23
24 presented twice, once with the masculine and once with the feminine clitic in the test sentence.
25

26 The same six verbs were used to construct test items in both [+Human] and [-Human]
27
28 conditions: *voir* 'see', *chercher* 'look for', *comprendre* 'understand', *(re)trouver* 'see again/find',
29
30 *choisir* 'choose', *connaitre* 'know'. Thus, the two conditions discussed here differed only with
31
32 respect to the type of antecedent available in the context: human beings in the [+Human]
33
34 condition and inanimate objects in the [-Human] condition.
35
36
37

38 <Insert Figure 3 about here>
39
40

41 In the sample test item illustrated in Figure 3, ([+Human] condition), *Anne* (referent #1)
42
43 and *David* (referent #2) are introduced as potential antecedents in the short context: *Tuesday*
44
45 *evening, Nicolas goes to the library to meet Anne or David.* The test sentence contains the
46
47 feminine clitic *la* and, thus, can only be interpreted as referring to *Anne*. Figure 4 illustrates an
48
49 experimental item from the [-Human] condition: both potential referents are inanimate objects,
50
51 in this case a *couch* (MASC) and *chair* (FEM): *When Nicolas needs to work at the library, he*
52
53
54
55
56
57
58
59
60

1
2
3 *prefers his comfortable chair or his relaxing couch.* The test sentence contains the masculine
4
5 clitic *le* that can only refer to the *couch*.
6
7

8
9 <Insert Figure 4 about here>

10 *Self-paced reading task*

11
12
13 The self-paced reading task was designed to test whether native speakers and L2 learners were
14
15 sensitive to gender mismatches with [-Human] as well as [+Human] antecedents. The test
16
17 contained 24 experimental items and 56 distractors that followed the same format as the test
18
19 items. In the [+Human] condition the experimental items tested participants' sensitivity to gender
20
21 mismatches with humans as potential antecedents. In the [-Human] condition the experimental
22
23 items tested gender mismatches with inanimate objects as potential antecedents.
24
25

26
27
28 Just to reiterate, the task did not test participants' lexical knowledge of gender since
29
30 gender was always unambiguously marked on the determiner. Each test sentence was presented
31
32 in a non-cumulative moving window format (Just, Carpenter & Woolley, 1982) and was
33
34 preceded by a short context presented in French (Figure 5). The context introduced a main
35
36 character and two other potential referents of different gender. In the [+Human] condition, these
37
38 two potential referents were a human male and a human female, e.g. *prince & princess* in the
39
40 [+Human] condition in Figure 5. In [-Human] condition these two referents were inanimate
41
42 common nouns of different (grammatical) gender, e.g. *train & car*. Items in both conditions were
43
44 designed so that only one of the potential referents was discourse-prominent, therefore creating a
45
46 gender expectation for the clitic in the test sentence. Each test sentence was followed by a yes-no
47
48 comprehension question. The number of yes and no answers was balanced for each participant
49
50 within the entire task. The pronoun in the test sentence either matched or mismatched the gender
51
52 of the discourse-prominent referent⁴ (e.g. *prince* in the [+Human] condition and *train* in the [-
53
54
55
56
57
58
59
60

Human] condition).

<Insert Figure 5 about here>

Results

Off-line task: Picture selection

As a reminder, here we analyze two conditions of the picture selection task: [+Human] and [-Human] conditions. As expected, native speakers and advanced learners performed very accurately on both conditions – accuracy rate of 94% and above.⁵ Since the distractor picture always matched the clitic’s gender, errors in computations of gender were the most revealing when participants chose “gender inappropriate” and “both referents are possible” pictures. Furthermore, since the number of “gender inappropriate” responses was extremely low across groups and conditions (no more than 6%), we combined “gender inappropriate” and “both referents are possible” responses into one response category: “gender error”. Figure 6 visually presents these results as a proportion of gender errors for each group and each condition.⁶

<Insert Figure 6 about here>

We analyzed gender errors using a 2×4 repeated-measures ANOVA with condition as a within-subjects factor and group as a between-subjects factor. The test revealed a statistically significant interaction between condition and group (Condition \times Group) in the by-participant and the by-item analysis ($F_1(3,126) = 3.58, p = .02$; $F_2(3,20) = 3.71, p = .03$). The Bonferroni post-hoc tests analyzed by participant revealed that intermediate and beginning learners made more “gender errors” in the [-Human] condition than in the [+Human] condition ($p = .02$ and $p < .001$ respectively). The differences in gender errors between [-Human] and [+Human] conditions for advanced learners and native speakers were not statistically significant ($p = .9$ and $p = .35$ respectively).

On-line Task: Self-paced Reading

The self-paced reading task presented a higher level of difficulty to our participants. Unlike the picture selection task, where the contexts were short and mostly contained vocabulary introduced in the first year of college French, the contexts in the self-paced reading task tended to be longer and included more advanced vocabulary (e.g. *la bonne* ‘the maid’ or *le jardinier* ‘the gardner’). Moreover, while pictures possibly alleviated some processing pressure in the picture-selection task, in the self-paced reading task L2 learners had to solely rely on verbal processing, which is harder at lower levels of proficiency. Therefore, it was important to make sure that the L2 learners were able to accurately perform the task and used gender information to correctly interpret the test sentences.

In order to determine whether the participants actually processed the sentences for information and extracted target-like meaning we calculated two types of comprehension accuracy scores: percentage of correct answers for the entire task and percentage of correct answers for the clitic sentences/test items. If the participants answered the yes-no questions at chance, we would expect an accuracy rate of 50%. For the overall task, beginners answered 61% of comprehension questions accurately, intermediate—65%, advanced learners—82%, native speakers—87%. However, for the test items, only native speakers and advanced L2ers correctly identified clitics’ referents at an above chance rate: 84% and 76% respectively. Beginning L2 learners answered 52% of questions correctly and intermediate 54%. This analysis led us to believe that the task was overly complex for beginning and intermediate L2 learners. Therefore, reading time results of the beginning and intermediate groups were not included in the analysis we present here⁷.

1
2
3 We analyzed test sentence reading times per segment, excluding the first two segments
4 that were repeated in each sentence throughout the experiment (*Voilà pourquoi...* 'That's
5 why...'). We further excluded extreme reading times from the analysis. In the native group, we
6 removed all values that exceeded 2000 milliseconds. Since reading times of L2 learners are
7 generally longer than those of native speakers, it did not seem appropriate to determine outliers
8 using the same cutoff point for L2 learners and native speakers. Therefore, for the advanced L2
9 group we removed all values exceeding 2 SDs from the mean calculated per segment. This
10 affected 1% of native speakers' data and 4% of the advanced learners' data.

19
20
21

22 We would like to remind the reader that the experimental design had two (within-
23 subjects) independent variables. The first variable was gender match/mismatch between the clitic
24 and the discourse-prominent antecedent, and the second variable was the [\pm Human] condition.
25 Before analyzing the results by condition, we compared reading times of gender matching and
26 gender mismatching sentences. We performed a 2×2 repeated-measures ANOVA test for the
27 reading times for each of the five sentence segments: the subject⁸, the clitic, the verb, and the
28 penultimate sentence segment, the preposition. We found no statistically significant main effect
29 or interaction on the subject nor on the clitic. We found a statistically significant main effect of
30 gender match/mismatch for the verb and the preposition. These results are reported in Table 2.

39
40
41
42

43 <Insert Table 2 about here>
44
45

46 To determine whether the differences in reading times of sentences with gender matching
47 and mismatching clitics were statistically significant in [$-$ Human] as well as in [$+$ Human]
48 condition, we analyzed reading times for each segment by condition. These word-by-word
49 reading times are graphically presented in Figure 7. We performed a $2 \times 2 \times 2$ repeated-measures
50 ANOVA test. Our within-subjects variables were [\pm Human] condition and Gender (Mis)match
51
52
53
54
55
56
57
58
59
60

1
2
3 and the between-subjects variable was Group (natives and advanced). Main effects, two- and
4 three-way interactions for each analyzed segment are presented in Table 3. Finally, in analyzing
5 the results we were primarily interested in whether native speakers and advanced L2 learners
6 were sensitive to gender mismatches. Therefore we focused on these contrasts leaving aside the
7 general differences between reading times in [+Human] vs. [-Human] conditions. If detected,
8 such contrasts could be the artifact of the experimental design since it was impossible to control
9 for the impact of the differences in [\pm Human] contexts on the processing of the test sentences.

10

13
14
15
16
17
18
19
20 <Insert Figure 7 about here>

21
22 <Insert Table 3 about here>

23
24
25 The differences between gender matched and gender mismatched sentence reading times
26 on the subject (segment 3) and the clitic (segment 4) were minimal and did not produce any
27 statistically significant results. The ANOVA on the reading time of the verb (segment 5), the
28 segment immediately following the clitic, revealed a three-way interaction of
29 Condition \times Gender (Mis)Match \times Group in the by-subject analysis ($F_1(1,63) = 4.5, p = .04$)
30 and a main effect of condition in the by-item analysis ($F_2(1,22) = 7.8, p = .01$). The post-hoc
31 Bonferroni test of the data grouped by subject showed that while Native speakers took longer to
32 read verbs that followed clitics of mismatched gender in both [+Human] ($p = .03$) and [-Human]
33 conditions ($p = .002$), advanced L2 learners were only sensitive to gender mismatches in the
34 [+Human] condition ($p = .02$), but not in the [-Human] condition (advanced: $p = .93$).

35
36
37
38
39
40
41
42
43
44
45
46
47
48 In both by-participant and by-item analyses, both groups were sensitive to gender
49 mismatches on the preposition following the verb (*avec* 'with' in the example given in Figure 5).
50 The ANOVA revealed a main effect of Gender (Mis)Match ($F_1(1,63) = 4.6, p = .04$; $F_2(1,22) =$
51
52
53
54
55
56
57
58
59
60
61 11.6, $p = .003$). We also detected a main effect of Condition in the by-participant analysis and a

1
2
3 two-way interaction between Condition \times Gender (Mis)Match in the by-item analysis (see Table
4
5 3 for the results). The last two results address differences between [\pm Human] conditions and not
6
7 between gender (mis)matches. As discussed above, such differences between conditions were
8
9 hard to avoid in designing the experiment and are not directly relevant to the research questions
10
11 pursued here.
12
13

14
15 Going back to the differences between gender matched and gender mismatched
16
17 sentences, the contrasts in reading times detected at the preposition (6th segment) are visually
18
19 presented in Figure 8. Even though the difference between gender matching and gender
20
21 mismatching sentences in the [$-$ Human] condition in the advanced L2 group was small, it was in
22
23 the predicted direction and statistically significant. Therefore, it is important to point out that
24
25 native speakers and, crucially, advanced L2 learners were sensitive to gender incongruity in both
26
27 conditions.
28
29

33
34
35

36 Discussion

37
38 In order to understand how L1 lexical combinations of morphosyntactic and semantic features
39
40 affect L2 knowledge of French pronouns and how this knowledge develops over time, we
41
42 conducted two experiments with native speakers and L2 learners of French of different
43
44 proficiency. Since we were primarily interested in which features of pronouns were easier to
45
46 access and process, we used a picture selection task and a self-paced reading task. The two tasks
47
48 differed dramatically in their level of difficulty. The picture selection task was less demanding
49
50 than the self-paced reading task, as evidenced by ceiling performance on the former by the native
51
52 speakers and the advanced L2 learners. The self-paced reading task, on the other hand, proved
53
54
55
56
57

overly complex for beginning and intermediate learners, whose results were excluded from further analysis of this task. This difference in the level of difficulty of the tasks allowed us to venture extrapolations about interlanguage development at different proficiency levels.

We focused on a language combination (L1 English – L2 French) where significant feature reassembly was required. First, L2 French lacks the [\pm Human] feature available in L1 grammar. Second, unlike English, L2 French lexically encodes GRAMMATICAL gender. Hence, while the L1 has NATURAL gender, the L2 GRAMMATICAL gender feature is new to the learners and they need to add it into pronoun feature bundles at the same time as they delete the native [\pm Human] feature. The experimental tasks were designed to relieve processing pressure by consistently providing GRAMMATICAL gender information through the determiner.

The participants in the current experiment were instructed learners of French. This means that they most likely received explicit metalinguistic explanations and in-class practice using object pronouns. Therefore, the interpretation errors we uncovered in our study provide further evidence for the sequential nature of second language acquisition, where target-like representations and target-like language use can be facilitated by instruction but also require extensive linguistic input and practice. On the one hand, we uncovered clear developmental patterns with respect to the tested property. On the other hand, since the participants were receiving instruction, even the beginners performed fairly well on the easier task that tested pronoun interpretation.

More specifically, in the picture selection task the beginner group demonstrated some ability to use GRAMMATICAL gender to interpret L2 pronouns. However, lexical encoding of NATURAL gender in the L1 pronominal paradigm (*he* vs. *she*) influenced beginner and intermediate L2 learners' off-line interpretations of *le* and *la*. L2 learners in these two groups

1
2
3 interpreted French object clitics more accurately when they referred to people than when they
4 referred to inanimate objects. Namely, the learners initially made fewer “gender errors”
5
6 interpreting NATURAL gender in the [+Human] condition than interpreting GRAMMATICAL gender
7
8 in the [–Human] condition. These results reflect the learners’ relative difficulty in using
9
10 GRAMMATICAL gender as compared to NATURAL gender to interpret French accusative clitics.
11
12

13
14
15 The advanced L2 learners, however, performed very accurately interpreting L2 pronouns
16
17 in the picture selection task. Their accuracy rate was equally high in both [+Human] and [–
18
19 Human] conditions (99%). This fact suggests that, at high proficiency levels, L2 learners used
20
21 GRAMMATICAL as well as NATURAL gender to interpret pronouns. Thus, the accuracy of the
22
23 advanced group on the picture selection task indicates that an eventual successful reassembly of
24
25 morphosyntactic features is possible. GRAMMATICAL gender has become part of the feature
26
27 specifications of the L2 clitic pronouns in the grammar of these learners, even though this feature
28
29 is not lexically encoded in L1 pronouns.
30
31
32
33

34
35 Turning to on-line processing of the gender feature, we can see that the specific feature
36
37 encoding in the L1 affected how gender mismatched pronouns were comprehended in real time.
38
39 However, these differences between L1 and L2 processing of gender mainly had to do with the
40
41 timing of the effects triggered by feature mismatches. Based on our results, we can conclude that
42
43 advanced L2 learners used GRAMMATICAL gender information to interpret L2 pronouns on-line.
44
45 We observed similar effects in the native and the advanced L2 group, even though these effects
46
47 appeared somewhat later in the case of L2 learners. Simply put, native speakers demonstrated
48
49 sensitivity to gender violation in processing verbs immediately following the clitic, while
50
51 advanced L2 learners demonstrated comparable sensitivity one segment later. This is not an
52
53 unusual finding in L2 processing research (e.g. Hahne, 2001; Coughlin & Tremblay, 2011).
54
55
56
57
58
59
60

1
2
3 Let us first discuss the reading time patterns detected on the segment immediately
4 following the clitic pronoun – the verb. Native speakers of French took longer to read verbs that
5 followed gender mismatched pronouns that referred to [+Human] as well as [–Human]
6 antecedents. When reading the verb, the advanced learners were only sensitive to gender
7 mismatches in the [+Human] condition, not to gender mismatches in the [–Human] condition.
8 Recall that in the off-line task the same advanced group used GRAMMATICAL gender to the same
9 degree as they used NATURAL gender and made virtually no errors in interpreting L2 pronouns
10 (1% error). This discrepancy between the off-line and the on-line impact of gender on pronoun
11 processing could indicate a lingering transfer effect on L2 processing from the native language
12 that has NATURAL gender, but not GRAMMATICAL gender in its inventory. The difference in the
13 L2 performance with GRAMMATICAL and NATURAL gender uncovered in the self-paced reading
14 task went undetected in the off-line performance.
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30

31
32 Now, let us turn to the reading time patterns observed two segments after the clitic was
33 encountered. Importantly, the advanced L2 learners took longer to read this segment in sentences
34 where the clitic did not match the gender of the discourse prominent antecedent. These
35 differences were detectable in both [+Human] and [–Human] conditions. These results suggest
36 that advanced L2 learners can detect GRAMMATICAL gender violations as well as NATURAL
37 gender violations, even though these processing reflexes are detectable (one segment) later in L2
38 reading time data than in native speakers' data.
39
40
41
42
43
44
45
46
47

48 Based on these off-line and on-line findings, we would argue that ultimately successful
49 feature reassembly is possible and it is evident in on-line processing as well as in off-line
50 interpretations of L2 pronouns. However, the influence of lexical encoding of L1
51 morphosyntactic features is detectable in on-line language processing for much longer (even at
52
53
54
55
56
57
58
59
60

1
2
3 advanced proficiency levels) than in the off-line performance. It manifests itself in three ways.
4
5 First, advanced L2 learners detected gender violations at the same processing moment as native
6
7 speakers in the [+Human] condition, but not in the [-Human] condition. Second, the asymmetry
8
9 between gender matching and gender mismatching sentences in the [-Human] condition became
10
11 detectable later in the reading times of the advanced L2 learners. Lastly, the distinctions between
12
13 the reading times in gender match and gender mismatch sentences were not as sharp in [-
14
15 Human] condition as in [+Human] condition for the advanced L2 learners, another possible
16
17 consequence of L1 transfer. In other words, gender mismatch based on the feature that exists in
18
19 L1 (i.e. natural gender) was more prominent for the advanced learners than the feature mismatch
20
21 that does not exist in the L1 (i.e. purely grammatical gender of [-Human] referents). Provided
22
23 these distinctions between off-line and on-line performance of the advanced L2 learners, we can
24
25 assume that a certain delay could exist between acquiring a representation and being able to
26
27 utilize it automatically on-line.
28
29
30
31
32
33

34 In this respect, our findings are in consort with accounts that postulate that variability in
35
36 L2 functional morphology may be due to lexical access difficulty (e.g., the Missing Surface
37
38 Inflection Hypothesis, Prévost & White 2000). According to these accounts, language has an
39
40 underlying and a surface representation. L2 learners are able to successfully acquire abstract
41
42 functional features, but may continue using forms that are underspecified for the said features.
43
44 Our results also square with usage-based accounts, e.g. L2 learners create weaker lexical
45
46 representations than native speakers because they use the L2 considerably less (Gollan, Montoya
47
48 & Werner, 2002). Finally, the findings are also compatible with capacity accounts, which argue
49
50 that problems with functional morphology are due to the lower processing capacity of L2
51
52 learners, which prevents them from consistently accessing and computing inflection and function
53
54
55
56
57
58
59
60

1
2
3 words in real time (Hopp, 2010; McDonald 2006). According to these accounts, computational
4
5 difficulties stem from paucity of memory resources, slower decoding and, in general, slower
6
7 processing. Our results also demonstrate that speaking of L1 influence on L2 development (as in
8
9 the Full Transfer Full Access Hypothesis, Schwartz & Sprouse, 1996) is no longer precise
10
11 enough. L1 influence is stronger in cases when feature reassembly is needed. Conceptualizing
12
13 transfer in terms of feature reassembly (e.g. adding new features, getting rid of L1 features,
14
15 reassembling features from L1 lexical bundles) allows us to better predict L1 transfer in general
16
17 and specific errors and developmental trajectories in particular.
18
19
20
21

22 The reading times pattern uncovered in our experiment could alternatively be explained
23
24 by the differences in “cognitive strength” (Carminati, 2005, p. 259) of natural and grammatical
25
26 gender in L2 processing. It is conceivable that natural gender is generally easier to process than
27
28 grammatical gender. For example, Carminati discovered processing differences for *pro*
29
30 resolution. In her experiment number mismatches were processed faster than gender mismatches.
31
32 The current experiment did not reveal such an asymmetry in the processing of grammatical and
33
34 natural gender by native speakers of French, a finding that echoes the results obtained by
35
36 Garnham et al. (1995). It is still conceivable that natural gender mismatches are more salient than
37
38 grammatical gender mismatches for L2 learners who have not achieved near-native proficiency
39
40 in an L2. In order to explore this possibility, further research is necessary into how grammatical
41
42 and natural gender mismatches are processed by L2 learners – especially speakers of L1s that
43
44 lexically encode both grammatical and natural gender.
45
46
47
48
49

50 Here we mainly focused on two types of gender, grammatical and natural gender, and
51
52 how L2 speakers, who do not have grammatical gender in their L1, acquire this new feature.
53
54 However, as discussed at the beginning of the article, the mismatch between French and English
55
56
57
58
59
60

1
2
3 also involves how the [\pm Human] feature is lexically encoded in the two languages. We are
4
5 leaving a more detailed investigation of this featural mismatch to further research. Future
6
7 research on the topic could also benefit from considering statistical properties of the linguistic
8
9 input potentially available to L2 learners. Earlier sensitivity to natural gender mismatches could
10
11 be the result of differences in the statistical distribution of human and non-human referents of *le*
12
13 and *la* in the input.
14
15

16
17 The FRH tested here has important pedagogical implications, encouraging L2 educators
18
19 to be mindful of L1-L2 differences. Teaching French object clitics pronouns to native speakers
20
21 of English is a good case in point. Even though the current study used a cross-sectional design
22
23 and did not look at the effects of instruction on acquisition, it still has implications for L2
24
25 pedagogy. When it comes to teaching French pronouns to Anglophones at college level, a
26
27 cursory examination of some textbooks as well the first author's personal experience reveal that
28
29 most pedagogical interventions are focused on training students in clitic production. Additional
30
31 evidence from Bruhn de Garavito's work on Spanish pedagogy of pronominal clitics suggests a
32
33 similar picture for teaching Spanish clitics. Namely, the forms are presented along with some
34
35 grammatical rules, followed by fill-in-the-blank practice activities, question-and-answer
36
37 activities prompting learners to use clitics in a sentence, and open-ended communicative
38
39 activities (Bruhn de Garavito, 2013).
40
41
42
43
44

45
46 Applied linguists, who conducted research on L2 acquisition of Romance clitics, have
47
48 called for a more careful attention to the input characteristics in teaching the topic (Bruhn de
49
50 Garavito, 2013; Erlam, 2003; Wust 2010). Classroom-based intervention studies found that
51
52 form-focused instruction is beneficial to L2 acquisition, including form-focused instruction of
53
54 French object pronouns (Erlam, 2003). However, several potentially important variables were
55
56
57
58
59
60

1
2
3 conflated in Erlam's study, for example the [\pm Human] distinction of pronominal antecedents.
4
5 Based on her cross-sectional study of L2 acquisition of French object clitics, Wust (2010)
6
7 recommended to provide students with ample possibilities in clitic detection and interpretation.
8
9 This approach to teaching French clitics goes in line with the tenets of Processing Instruction
10
11 (VanPatten 2004, 2012), where foreign language teachers are encouraged to provide a variety of
12
13 comprehension exercises to help learners pay attention and, ultimately, master L2 morphology.
14
15

16
17 Based on our results, we would like to join Wust and the proponents of Processing
18
19 Instruction in encouraging French instructors to provide students with more comprehension
20
21 activities, especially at the initial stages of instruction. Our findings lead us to believe that
22
23 activities targeting native-like interpretation of object clitics should be part of the curriculum
24
25 along with production exercises, especially in the case of Anglophone learners, where no one-to-
26
27 one mapping can initially be established between L1 and L2 forms. Learners should be trained to
28
29 resolve pronoun reference using lexically encoded information in a target-like way. Our results
30
31 also reinforce the voices in the field that call for practicing processing morphosyntactic and
32
33 semantic distinctions that might be problematic to L2 learners (Lardiere 2013; Slabakova &
34
35 García Mayo, 2013).
36
37
38
39
40
41
42
43

44 **Conclusion**

45
46 In this experimental study, we heed Clahsen et al.'s (2010) directive that "more fine-grained
47
48 linguistic distinctions are required to understand the nature of L2 morphological processing,
49
50 beyond the basic procedural versus declarative difference." (Clahsen et al., 2010, p. 39) The
51
52 combined picture that emerges from the results of two tasks suggests that the way the native
53
54 language bundles morphosyntactic and semantic features into various lexical items affects L2
55
56
57
58
59
60

1
2
3 development. These results by and large support the predictions of the FRH and provide further
4 motivation for conceptualizing L1 transfer in terms of mapping and reassembly of
5
6 morphosyntactic and semantic features in L2 lexical items. Changes in the interlanguage at
7
8 different proficiency levels were detected not only in the task that directly tested comprehension
9
10 but also in the on-line task. However, ultimately successful feature reassembly is possible, as
11
12 revealed by learners' off-line and, importantly, on-line performance. An area that still deserves
13
14 further investigation is the relationship between the ability to map/reassemble features as part of
15
16 linguistic representations and the ability to efficiently recruit these representations during
17
18 language processing. This, indeed, was one of the questions we asked in the introduction of the
19
20 paper. Based on our results, we propose that target-like on-line use of correct feature bundles
21
22 could constitute a third stage of interlanguage development that follows the mapping and the
23
24 reassembly stages. This last stage would most likely consist of strengthening links between
25
26 lexical nodes and corresponding gender classes (Hopp 2013), and automatizing procedural
27
28 knowledge of gender agreement (Segalowitz 2010; DeKeyser 2015). It remains to be seen how
29
30 such a view fares with an opposing view such as Parsing to Learn, where on-line sensitivity
31
32 precedes target-like interpretations (Dekydtpotter & Renaud, 2014). The proposal based on the
33
34 current findings would need further empirical verification with other properties, other language
35
36 combinations, and longitudinal data on feature reassembly.

18
19
20
21
22
23
24 ¹ See research on the role of clitics and their case marking in thematic role assignment
25
26 (McDonald & Heilenman, 1991) and its pedagogical treatment (VanPatten & Cadierno, 1993).

27
28 ² There are differences in how grammatical case values are lexically encoded in the two
29
30 languages. French lexically encodes (up to) four cases: NOM, ACC, DAT, OBL (*ils* vs. *les* vs.
31
32 *leur* vs. *à eux*). English only morphologically distinguishes between subject and object pronouns
33
34 (*they* vs. *them*). Here we focus on accusative pronouns. Lexical encoding of case values is
35
36 outside of the scope of the present research.

37
38
39
40 ³ We admit that the most natural way in French to express the idea of the last sentence is to use a
41
42 clitic left dislocation construction: *La rédaction, tu la cherches déjà depuis trois jours !* “The
43
44 composition, you’ve been looking for it for three days already !”

45
46
47 ⁴ We will refer to this (mis)match between the clitic and the discourse-prominent antecedent in
48
49 gender simply as “gender (mis)match” in the remainder of the paper.

50
51
52 ⁵ We would like to mention that accuracy rates among all proficiency levels in the picture
53
54 selection task could be perceived as high. For instance, the lowest accuracy score in the beginner
55
56 group was 54%. However, all the participants in the study were instructed learners. Provided that
57
58
59
60

1
2
3
4
5 explicit explanations of object pronouns and targeted practice in their use are almost always part
6
7 of French as a foreign language curriculum in the US, the number of interpretation errors
8
9 committed by the participants is non-negligible.
10

11 ⁶ Participants were allowed to leave questions unanswered. These cases did not exceed 1% of
12
13 answers per group for both conditions.
14
15

16 ⁷ As an anonymous reviewer points out, this measure limits the scope of the analysis and
17
18 prevents us from looking at earlier developmental stages. This information can be obtained in
19
20 future studies by creating an on-line task that would be manageable by beginning and
21
22 intermediate L2 learners. One of the possibilities to construct such a task could be to use the
23
24 visual world paradigm where disambiguation of objects is contingent upon gender processing.
25
26
27

28 ⁸ We analyzed reading times on the segment preceding the critical region, i.e. the clitic, to make
29
30 sure that there are no spurious effects before the participants see the critical region.

Appendix 1 Test items of the picture selection task

[+Human] condition

1. Mardi soir Nicolas vient à la bibliothèque pour rencontrer Anne et David. Nicolas : « Parfois, je la/le vois près de la fenêtre. »

- A. Anne
- B. David
- C. Anne ou David: les deux sont possibles
- D. La table/le dictionnaire

2. Le mercredi Nicolas va au parc avec Claire et Luc. Nicolas : « Le soir je le/la cherche partout. »

- A. Claire
- B. Luc
- C. Luc ou Claire: les deux sont possibles
- D. Le banc/la fleur

3. Paul et Nathalie font leurs études à Londres cette année et parlent anglais tout le temps. Nicolas : « Maintenant, je le/la comprends difficilement. »

- A. Nathalie
- B. Paul
- C. Nathalie ou Paul : les deux sont possibles
- D. Le livre/la brochure

4. Vendredi Marie et Pierre ont été malades et ne sont pas venus à l'école. Nicolas : « Heureusement, lundi je la/le retrouve en classe. »

- A. Marie
- B. Pierre
- C. Marie ou Pierre: les deux sont possibles
- D. La feuille de papier/le cahier

5. Jeudi les étudiants préparent des projets en groupes. Sabrina et Marc veulent travailler avec Nicolas. Nicolas : « Parfois je le/la choisis pour faire le travail. »

- A. Sabrina
- B. Marc
- C. Sabrina ou Marc : les deux sont possibles
- D. Le projecteur/la tablette

6. Philippe, Louissette et Nicolas font beaucoup d'activités: du judo, de la natation et du cheval. Ils passent beaucoup de temps ensemble. Nicolas: « Par conséquent, je la/le connais bien. »

- A. Louissette
- B. Philippe
- C. Louissette ou Philippe : les deux sont possibles
- D. La bibliothécaire/ Le bibliothécaire

1
2
3 [-Human] condition
4
5

6 1. Quand Nicolas doit travailler à la bibliothèque, il préfère sa chaise confortable et son canapé
7 relaxant. Nicolas : « Parfois, je la/le vois près de la fenêtre. »

- 8 A. la chaise
9 B. le canapé
10 C. la chaise ou le canapé : les deux sont possibles
11 D. la tablette/le dictionnaire
12

13
14 2. Quand il joue dans le parc, Nicolas cours vers la fontaine ou vers le banc. Nicolas : « Dans le
15 parc, je le/la cherche chaque dimanche. »

- 16 A. la fontaine
17 B. le banc
18 C. le banc ou la fontaine : les deux sont possibles
19 D. le terrain de football/la fleur
20

21
22 3. Les devoirs à l'école sont très difficiles. Nicolas doit lire plusieurs fois le journal et la
23 brochure distribués en classe. Nicolas : « Maintenant, je le/la comprends bien. »

- 24 A. la brochure
25 B. le journal
26 C. la brochure ou le journal : les deux sont possibles
27 D. le dictionnaire/la lettre
28

29
30 4. Le weekend Nicolas ne peut pas trouver son sac à dos et sa clé USB. Nicolas :
31 « Heureusement, lundi je la/le trouve à l'école. »

- 32 A. la clé USB
33 B. le sac a dos
34 C. la clé USB ou le sac a dos : les deux sont possibles
35 D. la ceinture/le baladeur MP3
36

37
38 5. Nicolas adore les fruits. Ses fruits préférés sont la pomme et le pamplemousse. Nicolas :
39 « Parfois je le/la choisis pour mon goûter. »

- 40 A. la pomme
41 B. le pamplemousse
42 C. le pamplemousse ou la pomme : les deux sont possibles
43 D. le kiwi/la banane
44

45
46
47 6. Nicolas passe beaucoup de temps dans le parc et à la ferme. Nicolas: « Par conséquent, je le/la
48 connais bien. »

- 49 A. la ferme
50 B. le parc
51 C. le parc ou la ferme : les deux sont possibles
52 D. le muse/la librairie
53
54
55
56
57
58
