"DISCOVERY" CRUISE 25 REPORT

(25th January - 28th March 1969)

DEEP WATER FORMATION IN NW MEDITERRANEAN
("MEDOC 1969")
TRIALS AND USE OF SHIPBOARD COMPUTER

N.I.O. CRUISE REPORT NO. 25
(issued June 1969)

CONTENTS

AIMS

The main purpose of this cruise was to contribute to a cooperative study of formation of deep water in the NW Mediterranean ("MEDOC 1969"). It was also the first cruise after the ship's computer had been fitted, and bringing it into operation was a major item in the scientific programme.
Subsidiary aims included further long-term current measurements in the Bay of Biscay, and observations of the Mediterranean outflow SE of Cape St. Vincent.

NARRATIVE

Left Aberdeen	25th January
Arr. Gibraltar	3rd February
Left. "	
Arr. Toulon	13th February
Left "	15th "
Arr. Toulon	3rd March
Left "	5th "
Arr. Barry	28th March.

"Discovery" sailed from Aberdeen after a refit during which the computer had been installed and extensive improvements made to the arrangement and size of laboratory spaces. After a smooth passage down the North Sea and English Channel, during which the worst of the post-refit chaos was cleared up, an attempt was made on 29th January to recover mooring No 26, laid on 4th November 1968 from HMS "Hydra" near 47°30'N, 8°20'W. The mooring was released successfully, but on recovery the wire was found to have pulled out of its termination just above the current meter. Dragging was unsuccessful, and passage was continued to the middle of the Bay of Biscay, where another mooring (No 27) was laid on 30th January. That mooring sank immediately, due to collapse of the subsurface floats at less than half the expected depth. This unexpected weakness of the subsurface floats was confirmed by testing one of those recovered from No 26 mooring, during the passage towards Gibraltar. It failed at 300m. depth. Tests were made of various items of acoustic equipment for moorings, and a trial lowering was made of the underwater camera, before arriving at Gibraltar.

Having taken on fuel and collected equipment landed there from HMS "Hydra", "Discovery" left Gibraltar on passage for 42°N, 5°E, near the area of maximum surface density located by "Hydra" in mid-January. This seemed the most promising area for the onset of deep water formation. Strong NW winds (50 kts) caused slow progress and the area was not reached until late on 6th February. A line of TSD and water sampling stations was started, and radio contact was made with the "Jean Charcot" and "Atlantis II". Next day the weather improved and two moorings were laid, with four current meters in each, in an area of high surface density where the "Atlantis II" was working with rotating floats measuring vertical motion. The wind increased from the NW again next day, when two neutrally buoyant floats were laid, and water sampling stations were worked instead of using the TSD which had become defective. Water sampling and float tracking continued, with interruptions by bad weather, until 12th February, when the weather improved sufficiently for a third mooring to be laid. Navigation depended almost entirely on satellite fixes, the moored buoys being only intermittently visible on the radar in the poor weather. The moorings were placed on either side of a front with well mixed dense water to the north and stratified water to the south. After two further hydrographic stations in the mixed water, course was set for Toulon.

The four other ships taking part in "MEDOC 1969" at that time - "Atlantis II", "Jean Charcot", "Bannock" and "Origny" were also in Toulon, and plans were made for further study of the well mixed water.

Leaving on 15th February, a reference station was worked just south of Toulon, and "Discovery" then returned to the patch of dense well mixed water. The wind increased to 50 knots, too rough to risk the TSD which had been repaired. Work was resumed early on 17th February with a detailed TSD survey of part of the well mixed area and its southern boundary. Adiabatic temperature gradients were found extending from the surface to more than 2 km depth in some places. The moored buoys were recovered and re-laid in more suitable positions in relation to the patch of mixed water. Six neutrally buoyant floats were laid, at a nominal depth of 500m, and were tracked until 25th February. A section of TSD and hydrographic stations was then worked from north to south through the area, and four more floats started, two at 500m which confirmed the cyclonic shear indicated by the previous floats, and two at 1500m which moved anticyclonically. The three moorings were recovered and seven more TSD dips made before returning to Toulon on 3rd March.

"Atlantis II" came in the same day and further discussions of the programme took place. "Discovery" sailed on 5th March, returning to the same area to find that the dense water had been covered by 100-500m. of less dense water. There had been no cold strong winds since 17th February, and it seemed that the downward mixing and active formation of new deep water had come to an end. During the next 12 days, the process of sinking and southward spreading of the dense water was observed by means of more TSD dips, re-laying the three moorings (one of which was picked up and re-laid yet again) and tracking 8 more neutrally buoyant floats. On 12th March, in the course of this float tracking an acoustic signal was found and mistakenly identified as a beacon on one of the moorings that was suspected of having gone adrift, and several hours were spent in trying to recover it, before it was recognized as coming from one of the Woods Hole rotating floats. By that time the "Atlantis II" had left the area. The motion at 500m depth was predominantly anti-cyclonic this time, with some southward component. Work continued in the area until 17th March, ending with a TSD section southwards as far as 41°N, after which "Discovery" set course towards the Straits of Gibraltar.

A buoy was anchored and several TSD stations worked, on 20th - 21st March near 36° 40'N, 8° 30'W, in the neighbourhood of a bay in the continental slope. The purpose of these observations was to determine whether the core of the highly saline Mediterranean outflow water followed round the curve of the bay. During the passage northward, two lowerings were made with the milwater camera. It had been intended that a near-bottom mooring, with one current meter, should be laid in the middle of the Bay of Biscay, but the deep buoyancy sphere leaked slightly on test and the mooring was not laid. On 25th March, two moorings, each with one current meter, were laid near 47° 30'N, 8° 20'W and left out for subsequent recovery in June. Another unsuccessful attempt was made at dragging for the remains of No. 26 mooring, and passage was resumed towards Barry, where "Discovery" arrived for the first time on 28th March.

NOTES ON EQUIPMENT AND OBSERVATIONS

For fuller details on any of these items, consult the persons named

1. COMPUTER (Crease, Hinde)

The installation of the IBM 1800 computer took place in the 2nd week of January amid the last minute chaos of the refit. Power was not available for the system until the day before sailing (apart from a brief temporary supply from the C.L.O.R.I.A. generator). However, no adverse effects of the transportation were noted.

During the first 3 legs of the cruise N.I.O.'s computer engineers were trained in maintenance and diagnostics on the 1800 by Mr. M. Whale of I.B.M. In spite of some bad weather the course was completed. How successful it was remains to be seen as in fact the 1800 system has been remarkably fault free, running for 24hrs a day for many days, even in heavy weather.

The only really unreliable peripheral equipment has been the off line Dura tape preparation and reproduction set, which was largely unserviceable except for the listing of paper tape output.

The on-line acquisition of data was tested out on the following observations (in between training periods)

a) Satellite navigator - no problems arose with this interface. Reliable fixes were obtained and errors that arose were due to need for manual intervention through lack of a complete program set.

b) Analogue inputs from ship's log, anemometer, wet/dry bulb temperatures. These were all basically satisfactory but suffered in usefulness through lack of calibration data.

c) Digital inputs from Echo-sounder console, crystal clock, gyro compass. The echo-sounder console worked well and all data was filed on disk. Some improvements are required for ease of operation. The digital clock and gyro both suffered from troubles in the interfaces supplied. The clock was not used at all and the gyro was intermittently malfunctioning so recourse was had to the computer's internal clock and an analogue gyro compass.

The cruise provided plenty of opportunity for first hand experience for all of us with the problems of discipline in wiring practice on board ship; avoidance of earth loops in the system and noise spikes on digital lines.

The adaption by Mr. Spatz of IBM of the TSX monitor system to operate with paper tape was successful and we have no reason to regret the decision to operate with paper tape rather than cards.

In summary, the system hardware proved reliable at sea. Our engineers were trained and the software appears capable of satisfying our needs.

2. ECHO SOUNDING (Swallow, Tucker)

Soundings were recorded every 10 mins. whenever this could be done without interference to other acoustic work. Several minor faults were repaired with less than 2 hours' total loss of soundings.

3. ELECTROMAGNETIC LOG (2 components) (Smith, Swallow, Tucker)

An analogue record of the two components of speed and ship's heading was made continuously throughout the cruise, and in the later part the speed components were logged by the computer. Both components of speed were calibrated relative to a radar buoy attached to a surface drogue. The sensing head was found to be free from corrosion and fouling when examined at the end of the cruise, and it was left in place for the following cruise.

4. METEOROLOGICAL RECORDING (Crease, Mrs. Edwards)

The routine observations made by the ship's officers were supplemented by Assmann psychrometer readings every 6 hours while in the NW Mediterranean, and by recording the outputs of resistance thermometers (wet and dry, port and starboard), and the solarimeter, on the Speedomax recorder.

5. MOORINGS AND CURRENT METERS (Gaunt, Gould)

After the misfortunes to the Biscay moorings on the way out, those in the Mediterranean were relatively successful. Their performance is summarized in Table II. All the Mediterranean moorings had surface buoys in addition to the main subsurface float, and these survived some severe storms without damage other than loss of two radar reflectors. Three Plessey current meters, borrowed from the Fisheries Laboratory, Lowestoft, were used on the first three Mediterranean moorings, and all three were lost, each for a different reason, through failures of parts of the meter or suspension frame, not of the moorings themselves.

6. NEUTRALLY BUOYANT FLOATS (Swallow)

Twenty-one floats were used in the Mediterranean work, and all but one gave useful results. The pulse generating circuits had been improved and had a much more stable repetition rate, greatly simplifying the problem of searching for floats. Acoustic ranges of well over 5 miles were regularly obtained in the nearly isothermal water. Particulars of the floats used are given in Table III.

7. TEMPERATURE-SALINITY-DEPTH PROBE (Sankey, Swallow, Tucker)

The type 9006 sea unit and all the recording equipment had been in use on board HMS "Hydra" in January, and was picked up by "Discovery" at Gibraltar. After only a few lowerings, the depth gauge became defective and could not be repaired on board. The new type 9040 sea unit had a very large depth-dependent error in salinity and high noise level. A replacement depth gauge for the type 9006 was borrowed from Liverpool and fitted at Toulon on 14th February; this worked well for the rest of the cruise. The 9040 sea unit was later found to have its depth compensation for salinity connected wrong way round, and worked satisfactorily when this was rectified. Calibration was effected by reversing a water bottle, attached just above the sea unit, at some depth on each lowering, and by reversing another water bottle on a separate wire at 10m depth when the sea unit was at that depth during recovery.

8. UNDERWATER CAMERA (Smith, Moorey)

This experiment was an attempt to detect salt fingers by photographing a pattern of black and white lines through approximately 2m of water, with the camera and flash cycling automatically. Lowerings were made on three occasions in the Atlantic, through the depth range of the Mediterranean outflow water. For the first two lowerings the camera was arranged horizontally, in the third one it was pointed downwards.

9. WATER SAMPLING AND ANALYSIS (McCartney, Moorey, Sankey, Swallow)

Twenty-seven hydrographic stations were worked, in addition to the check samples collected with the TSD. Temperature, salinity and dissolved oxygen were determined on these stations. Salinities were measured on an Autolab conductivity bridge which suffered from intermittent faults and gave values for the deep water systematically higher than those obtained by the "Jean Charcot", though in fairly good agreement with those of the "Atlantis II". In view of the uncertainties, duplicates were drawn from nearly all salinity samples at stations 6809 onwards for measurement at N.I.O. on the thermostat salinometer.

Large samples (approx 5l.) of surface water were collected at six stations for pesticide analysis by the Government Chemist.

TABLE II

MEDOC 1969 MOORINGS

NIO Serial No.	No. for Cruise	TIME Laid (GMT+1)	DATE Laid	TIME Recovered	DATE Recovered	Nominal Depth (m)	Meter	Remarks
28	I	1735	7.II	1850	21.II	20	P	Lost meter
						100	Be	Good data
						Bad Ref. <300	Be	Good data
						1500	Br	Data apparently good
29	II	2230	7.II	1630	19.II	20	P	Lost meter
						100	Be	Data good
						300	Be	Tape fault. No data
						1500	Br	Data lost in processing
30	III	1211	12.II	1840	20.II	20	P	Lost meter
						100	Be	Good data
						300	Be	Good data
						(to 1200/14 only) short record 1500	Br	Data apparently good)
31	IV	1713	20.II	1525	28.II	100	Be	Tape fault. No data
						300	Be	Good data
						1550	Br	Data lost in processing
						2200	Br	Data lost in processing
32	V	1622	21.II	1735	2.III	100	Be	Good data
						300	Be	Good data
						1500	Br	Data apparently good
33	VI	1615	22.II	1356	1.III	100	Be	Tape fault. No data
						(to de Lone) 300	Be	Good data
						1500	Br	Data apparently good
34	VII	1740	6.III	1142	11.III	100	Be	Good data
						300	Be	Good data
						(to be done) 900	Be	Good data
						1500	Br	Data apparently good
35	VIII	1638	7.III	1015	16.III	100	Be	Good data
						300	Be	Good data
						(Tape did not run) 1500	Br	Data apparently good
36	IX	1756	8.III	1041	15.III	100	Be	Good data
						(to be done) 300	Be	Good data
						900	Br	Data lost in processing
						(redeployed) 1500	Br	Data apparently good
37	X	1931	11.III	1525	16.III	100	Be	Good data
						300	Be	Good data
						900	Be	Good data
						(very short) 1500	Br	Data apparently good

P = Plessey
Be = Bergen
Br = Braincon

"Data apparently good" means that the record has been developed and looks O.K. but has not been read yet.

TABLE III
