Abstract

1
2
3 Despite being a universal human attachment behavior, little is known about individual
4 differences in crying. To facilitate such examination we first recommend shortened versions of
5 the attitudes and proneness sections of the Adult Crying Inventory using two independent
6 samples. Importantly, we examine attachment orientation differences in crying proneness and
7 test the mediating role of attitudes toward crying in this relationship. Participants (Sample 1
8 $N=623$, Sample 2 $N=781$), completed online measures of adult attachment dimensions
9 (avoidance and anxiety), attitudes towards crying, and crying proneness. Exploratory factor
10 analyses in Sample 1 revealed four factors for crying attitudes: crying helps one feel better;
11 crying is healthy; hatred of crying; and crying is controllable; and three factors for crying
12 proneness: threat to self; sadness; and joy. Confirmatory factor analyses in Sample 2 replicated
13 these structures. Theoretically and statistically justified short forms of each scale were created.
14 Multiple mediation analyses revealed similar patterns of results across the two samples, with the
15 attitudes 'crying is healthy' and 'crying is controllable' consistently mediating the positive links
16 between attachment anxiety and crying proneness, and the negative links between attachment
17 avoidance and crying proneness. Results are discussed in relation to attachment and emotion
18 regulation literature.

Provisional

1 **Introduction**

2 Crying, defined as tearing for emotional reasons, is unique to humans and universal (Vingerhoets
3 & Cornelius, 2001). Crying can be hard to control, difficult to falsify, and is imbued with an
4 intensity unparalleled by other forms of emotional expression (Vingerhoets & Cornelius, 2001),
5 providing a unique window into how people experience, regulate, and communicate emotions.
6 Crying is displayed from birth into adulthood. Adults cry with varying frequency and for a
7 variety of reasons (Vingerhoets, Boelhouwer, Tilburg, & Heck, 2001) and substantial variation is
8 observed in proneness to crying (Vingerhoets, Van Tilburg, Boelhouwer, & Van Heck, 2001).
9 Crying is a primary attachment behavior and attachment orientations (beliefs and strategies
10 concerning emotions and interpersonal relationships; Bowlby, 1969; Mikulincer & Shaver, 2007)
11 are fundamental for understanding crying. Evidence examining crying from an attachment
12 perspective (Laan, van Assen, & Vingerhoets, 2012), however, is sparse and the underlying
13 mechanisms of this relationship poorly understood. We explore attachment orientation
14 differences in adult crying proneness, and the mediating role of attitudes towards crying.
15

16 **Crying in adulthood**

17 Adult crying reflects both positive and negative emotions (Vingerhoets, Boelhouwer, et al.,
18 2001). Bindra (1972) found that causes of crying often related to feelings of elation, dejection, or
19 anguish. Similarly, Kottler (1996) identified physiological responses, redemption, connection to
20 others, grief and loss, despair, joyful and aesthetic transcendence, anger and frustration, and
21 manipulation of others, whereas Scheirs and Sijtsma (2001) identified distress, sadness, and joy
22 (see Vingerhoets et al., 2001, for a review). Crying has intrapersonal and interpersonal functions.
23 Theorists have argued that crying may be of intrapersonal therapeutic utility by facilitating
24 emotional processing and acceptance of loss (Hendriks, Nelson, Cornelius, & Vingerhoets, 2008;
25 Nelson, 2005). Interpersonally, crying is a key attachment behavior, intended to elicit care and
26 comfort from close others throughout life (Bowlby, 1969; Nelson, 2005). Hendriks et al. (2008)
27 argue that the social support elicited by crying fully explains its benefits. Empirical evidence on
28 the outcomes of crying (including its benefits), however, is scarce. Moreover, where they exist,
29 findings are mixed (Cornelius, 1997; for a review see Hendriks et al., 2008). Nevertheless, the
30 belief that crying is healthy or beneficial is widespread (Cornelius, 1997). The functions of
31 crying are moderated by individual differences. There is notable variation in the frequency with
32 which adults report crying in everyday life (Hastrup, Kraemer, Bornstein, & Trezza, 2001). As
33 well as established gender differences in crying behaviors (females cry more often; Frey, 1985)
34 crying proneness has been negatively associated with both alexithymia and ‘distancing’ coping
35 strategies, and positively associated with neuroticism (Vingerhoets, Van den Berg, Kortekaas,
36 Van Heck, & Croon, 1993). But the source of this variation is not well understood.
37

38 **Adult attachment and crying**

39 Attachment theory holds that humans are innately predisposed to form and maintain close
40 emotional bonds with select others throughout life (Bowlby, 1969). Individual differences in
41 adult attachment are conceptualized along the dimensions of avoidance of intimacy (i.e.,
42 deactivating strategy), and anxiety about abandonment (i.e., hyperactivating strategy). Those
43 high in attachment avoidance respond to attachment-related negative affect by downplaying its
44 importance, suppressing emotional responses, and orienting away from caregivers (Mikulincer &
45 Shaver, 2007). Those high in attachment anxiety hyperactivate and express negative affect in an
46 attempt to seek proximity to caregivers (Mikulincer & Shaver, 2007). Attachment security,

1 which involves comfort with emotional expression, and the ability to regulate negative affect
2 using internal resources, is represented by low scores on both dimensions (Brennan, Clark, &
3 Shaver, 1998; Mikulincer & Shaver, 2007). Early work on adult attachment categorized
4 individuals into attachment styles based on combinations of high versus low avoidance and
5 anxiety (Bartholomew & Horowitz, 1991).

6
7 Attachment behaviors, such as crying, ensure that humans remain in close physical proximity to
8 their attachment figures when threat is experienced (Ainsworth, Blehar, Waters, & Wall, 1978;
9 Bowlby, 1969; Cassidy & Shaver, 1999). In infancy and childhood, threat detection mechanisms
10 are sensitive, thus crying behaviors are common (Zeifman, 2001). In adulthood, thresholds for
11 crying are much higher but crying can still be evoked by attachment threat such as prolonged or
12 unexpected separation (Nelson, 2005; Zeifman, 2001). Adults may cry to gain care from others
13 directly (especially attachment figures). However, crying in solitude can also be conceived as
14 seeking support from internalized representations of caregivers, which serves the same soothing
15 and down-regulation functions (Nelson, 2005).

16
17 Preliminary evidence supports the existence of theoretically sensible attachment differences in
18 adult crying behavior. Using single-item measures of both attachment and crying, Bartholomew
19 and Horowitz (1991) found that those with a high-avoidant style reported lower crying frequency
20 than those with low-avoidant style. Additionally, those with a high-anxious style reported the
21 most frequent crying and the greatest tendency to cry in front of others (vs. alone). Using the
22 same categorical attachment measure, Laan et al. (2012) examined self-reported crying
23 proneness and crying in response to hearing attachment-themed songs and found that those with
24 a high-avoidant attachment style reported the lowest proneness to crying, and the least intense
25 crying in response to music. Those with high anxious styles reported crying more for negative
26 reasons and less for positive reasons, and more intensely in response to music, than those with a
27 secure style. Finally, Denckla, Fiori, and Vingerhoets (2014) examined the relationship between
28 attachment dimensions and vicarious crying proneness (i.e., propensity to cry when experiencing
29 events through books or films) and found that attachment anxiety was positively related to
30 vicarious crying for reasons associated with attachment, society, sentimentality, and compassion.
31 Attachment avoidance was negatively related to vicarious crying concerning themes of
32 attachment but positively related to society and sentimentality crying. By focussing on vicarious
33 crying proneness, however, the cited research did not include real-life and personal experiences,
34 the most common everyday triggers of crying (Bindra, 1972).

35
36 To date there has been no systematic examination of attachment differences in the full range of
37 crying contexts, using reliable dimensional measures. Moreover, the mechanisms underlying
38 attachment differences in adult crying have not been examined. There are two main reasons that
39 attitudes toward crying should be considered as mechanisms. Firstly, an individual's attachment
40 orientation is manifested behaviourally via the accessibility of cognitive schemas, containing
41 attitudes and beliefs relating to emotions and interpersonal relationships (Collins & Read, 1994).
42 The two dimensions of attachment insecurity (avoidance and anxiety) have specific attitudinal
43 components related to the expression of emotions, whereby avoidance is associated with a
44 preference not to reveal one's true feelings or acknowledge those of others, and anxiety is
45 associated with a desire for the emotional intimacy that results from disclosure (Brennan et al.,
46 1998). Secondly, outcomes related to emotional expression are known to be influenced by

1 attitudes, for example, in restricted emotionality in men (Wong, Pituch, & Rochlen, 2006), eating
2 psychopathology (Meyer, Leung, Barry, & De Feo, 2010), and psychological distress in a high
3 stress context (J. Brown & Grover, 1998). It is also known that attitudes towards emotional
4 expression partially mediate the link between social anxiety and the avoidance of emotional
5 expression (Spokas, Luterek, & Heimberg, 2009). Given the attitudinal components of cognitive
6 representations of attachment, and the tendency for attitudes to predict outcomes related to
7 emotional expression, we sought to examine attitudes towards crying as potential mediators of
8 the link between attachment orientation and crying proneness.

10 **The current research**

11 In two cross-sectional samples, we examine the relationship between attachment orientation,
12 attitudes towards crying, and crying proneness. The motivations for our work are threefold.
13 Firstly, we sought to examine the factor structure of the proneness and attitudes components of
14 the most commonly-used measure of crying - the Adult Crying Inventory (ACI, Vingerhoets,
15 2001, cited in Vingerhoets & Cornelius, 2001). While some measurement papers exist for the
16 proneness scale (Laan et al., 2012; Scheirs & Sijtsma, 2001), to the best of our knowledge, no
17 published works have examined the factor structure of the attitudes scale. This would provide the
18 basis for us to examine our hypotheses in a robust way. Moreover, given that these scales are
19 long (i.e., 55 and 24 items respectively), we hoped to identify theoretically and statistically
20 derived short forms to facilitate future crying research.

22 Secondly, we sought to examine how the dimensions of attachment avoidance and anxiety
23 predict crying proneness. We did so both by assessing self-reported crying proneness (Samples 1
24 and 2) and also by asking respondents about their last experience of crying in terms of recency,
25 intensity, and duration (Sample 2). Reporting a more recent (vs. more distal) experience provides
26 a more implicit index of crying proneness. In line with past research that used categorical
27 attachment measures or limited crying measures (Bartholomew & Horowitz, 1991; Denckla et
28 al., 2014; Laan et al., 2012), we predicted that (H1a) attachment avoidance would negatively
29 predict crying proneness, and (H1b) attachment anxiety would positively predict crying
30 proneness. Similarly, in terms of most recent episode we hypothesized that (H2a) avoidance
31 would negatively predict crying recency, duration, and intensity, and (H2b) anxiety would
32 positively predict crying recency, duration, and intensity.

34 Finally, we sought to examine for the first time the role of attitudes towards crying. Based on the
35 above rationale concerning the role of attitudes in attachment cognitive representations and as
36 modulators of behaviour, we predicted that (H3) attitudes towards crying would mediate the
37 relationships between attachment avoidance and anxiety, and reported crying behaviour (i.e.,
38 proneness and most recent episode). We defer discussion of specific attitude dimensions until
39 clarification of their factor structure (see below).

42 **Method**

44 **Participants and procedure.** Ethical approval was received from the University of Bristol
45 Ethics Committee (Sample 1) and the University of Southampton Ethics Committee (Sample 2)
46 prior to commencing recruitment. For Sample 1 (N=623), respondents were recruited via student

1 mailing lists in three UK HE institutions. Personal contacts of the researchers also electronically
 2 distributed links to the study among non-student groups. Of the sample, 336 were female, 223
 3 were male, and 64 did not disclose their gender. Participants were aged 18-81 ($M=23.00$,
 4 $SD=7.10$). There were missing nationality and ethnicity data (due to system error), but of the
 5 total sample, 54.4% were British (45.6% missing). Of the total sample, 53% were White, 1.4. %
 6 were Black, and 3.7% were Asian (42.4% missing). Participants took part in exchange for prize
 7 draw entry for Amazon vouchers. Missing data on the variables of interest meant that mediation
 8 analyses were undertaken with $N=527$, or $N=526$ for analyses where Threat to Self was the
 9 dependent variable.

10
 11 For Sample 2, participants ($N=781$) were 256 undergraduates at the University of Southampton,
 12 who received course credit, and 525 volunteers who accessed the study via the internet (e.g.,
 13 www.socialpsychology.org). They were invited to a study on ‘personality and expressing
 14 emotions’ and completed the measures below online in one session among other unrelated
 15 measures. The sample comprised 572 women and 208 men (1 undisclosed gender) aged 16-65
 16 ($M=23.51$, $SD=8.46$). Most were from the USA (46%) or UK (42%), and reported being of
 17 Caucasian (76%), Asian (6%), or Black (5%) ethnic origin.

20 Measures.

22 *Sample 1*

23 Questionnaires included measures of attachment orientation, attitudes towards crying, crying
 24 proneness, and a brief demographics section. Attachment and crying measures were
 25 counterbalanced to eliminate any priming effects from one measure to the other.

26
 27 Attachment orientation was measured using the Experiences in Close Relationships scale (ECR;
 28 Brennan et al., 1998), adapted for dispositional, rather than romantic attachment (e.g. Rowe &
 29 Carnelley, 2003). The ECR is the most widely used measure of adult attachment and comprises
 30 two 18-item dimensions, tapping attachment avoidance (e.g., ‘*I prefer not to show people close*
 31 *to me how I feel deep down.*’) and attachment anxiety (e.g. ‘*I worry a lot about my*
 32 *relationships.*’). Items were rated from 1 (*strongly disagree*) to 7 (*strongly agree*). Cronbach’s
 33 alphas were .91 for avoidance and .92 for anxiety, which is consistent with previous research
 34 (Brennan et al., 1998).

35
 36 Participants completed the Adult Crying Inventory (ACI; Vingerhoets, 2001, cited in
 37 Vingerhoets & Cornelius, 2001). The 24-item section on attitudes towards crying covers a range
 38 of positive and negative attitudes (see Table 1 for items, 1=*strongly disagree* 7=*strongly agree*).
 39 Given that there is no published factor structure for this scale, we used factor analysis to derive
 40 subscales.

41
 42 The ACI proneness section asks the respondent to indicate how often they cry in each of 55
 43 situations (see Table 2 for items; 1 = *never*, 7 = *always*). The scoring of this measure in past
 44 research has been inconsistent. For example, Laan et al. (2012) proposed two dimensions
 45 reflecting positively and negatively valenced crying proneness. Furthermore, Scheirs and Sijtsma
 46 (2001) derived a three factor solution (using factor analysis, see Table 2) depicting crying

1 through distress, sadness, and joy, but also acknowledging one and two factor solutions. Due to
 2 the multiple published solutions, and the novelty of using this measure with UK samples, we
 3 conducted our own factor analysis and compared it against Scheirs and Sijtsma (2001).

5 **Sample 2**

6 Participants first completed the ACI as in Sample 1. Item orders within each section were
 7 randomized.

8
 9 In addition, participants completed items from the ACI concerning their most recent crying
 10 episode. They gave a short description of “the most recent situation or event that made you feel
 11 tears in your eyes.” Participants then indicated how long ago the episode occurred (1=*less than a*
 12 *day*, 7=*more than a year ago*—reverse-coded), how long it lasted (1=*less than 5 minutes*,
 13 7=*repeatedly recurring spells*), and how intense their crying was (1=*just wet eyes*, 4=*wet eyes*,
 14 *sobbing, howling, body movements and vocalizations*). In all cases, higher scores reflected
 15 stronger crying tendencies.

16
 17 Participants completed the Experiences in Close Relationships Scale Brief Version (Wei,
 18 Russell, Mallinckrodt, & Vogel, 2007). Participants responded to the 6 avoidance items ($\alpha = .81$)
 19 and the 6 anxiety items ($\alpha = .74$) in randomized order (1=*strongly disagree*, 8=*strongly agree*).

22 **Results**

23
 24 First, we describe the data reduction analyses undertaken to establish subscales of the attitudes
 25 and proneness sections of the ACI with Sample 1. We then describe the replication of the factor
 26 structure in Sample 2.

27
 28 Second, we describe multiple mediation analyses examining the extent to which the attitudes
 29 factors mediate the relationship between attachment orientation and crying proneness in Sample
 30 1. We then describe the replication of these results in Sample 2.

31
 32 Third, we describe our analyses pertaining to most recent crying episode (Sample 2).

35 **Exploratory factor analysis (Sample 1)**

36 **Attitudes towards crying.** We performed an exploratory factor analysis using principle axis
 37 factoring with promax rotation to allow factors to be correlated. The scree plot identified the
 38 presence of four factors, which accounted for 59.7% of the variance (Table 1). The first factor
 39 contained seven items reflecting the belief that crying helps one feel better (hereafter “Feels
 40 Better”). The second factor contained nine items and referred to the belief that crying is healthy
 41 (“Healthy”). The third factor contained four items reflecting a very negative view of crying
 42 (“Hatred”). The fourth factor contained four items and most referred to the belief that crying can
 43 versus cannot be controlled (“Control”).

44
 45 Due to the length of the ACI and the likely redundancy within subscales, we sought to derive a
 46 short-form of the scale for use in analyses. We selected items on the basis of: (i) retaining the

1 strongest-loading items; (ii) eliminating conceptual redundancy (e.g., for Feels Better, item 15
 2 was eliminated for being too similar to item 10); (iii) item distributions (e.g., item 14 was
 3 eliminated for eliciting majority disagreement); and (iv) cross-loadings $>.40$ (e.g., item 20 was
 4 eliminated), while (v) retaining a consistent conceptual meaning (e.g., item 24 and 22 were
 5 eliminated because they referred to controlling other people, rather than one's own tears). In all,
 6 we selected 4 items from each of Feels Better and Healthy, 3 items from Hatred, and 2 items
 7 from Control, thus reducing the scale from 24 items to 13 items. Each short-form scale score
 8 consisted of a mean of the item scores. Given that two of the subscales contain only 2 or 3 items,
 9 we recommend that future research seeks to expand these scales to 4 items to maximize their
 10 reliability and conceptual coverage.

11
 12 To assess the validity of the short-form scales, we correlated them with the full scales derived
 13 from the factor analysis. All four short-form scales correlated with their longer counterpart $>.80$,
 14 suggesting that they adequately capture each factor (Table 3). Cronbach's alphas for the first
 15 three subscales were $>.70$ (Table 3). The two items in the Control scale were positively
 16 correlated, $r = .32$, $p <.001$. Similar inter-item correlations within a longer scale would yield an
 17 adequate alpha, so additional items are particularly important for future use of this subscale.
 18 Given the conceptual importance of the construct of control (which partially mediated between
 19 social anxiety and emotional expression; Spokas et al., 2009), we opted to retain this subscale.
 20 Table 3 also shows the means and SDs for each subscale, by gender. Women scored significantly
 21 higher than men on all subscales, except for Hatred, where men scored significantly higher than
 22 women.

23
 24 **Crying proneness.** We performed an exploratory factor analysis again using principle axis
 25 factoring with promax rotation for the crying proneness section of the ACI. The scree plot
 26 indicated the presence of three factors, which together accounted for 49.5% of the variance
 27 (Table 2). The first factor contained 21 items referring to a range of contexts concerning an
 28 affront to one's integrity or ego, and so we labeled it "Threat to Self." The second factor
 29 contained 19 items mostly referring to happy or positive contexts ("Joy"). The third factor
 30 contained 15 items, most of which referred to sad or loss contexts ("Sadness"). As shown in
 31 Table 2, the solution was very similar to that reported by Scheirs and Sijtsma (2001). All items
 32 fell into the same factors as in Schiers and Sijtsma's except for one in Threat to Self (which they
 33 labeled "Distress"), three in Joy, and three in Sadness—all of which loaded $<.50$ on our factors.
 34

35 To shorten the proneness section of the ACI, we selected 6 items for each subscale, thus reducing
 36 the items from 55 to 18 (see Table 2 for items). We followed the same criteria as those described
 37 for shortening the attitudes section. In addition, where it was possible to do so without risk of
 38 losing important conceptual coverage, we eliminated items that cross-loaded higher than $.30$ on
 39 another factor. There were two exceptions to this: item 15, "when someone does something very
 40 special for me/someone," loaded most strongly onto Joy but also onto Sadness. Item 31, "when a
 41 tragic event happens," loaded most strongly onto Sadness but also negatively onto Joy. However,
 42 we opted to retain these items due to their important construct coverage. Also, the process of
 43 reducing subscales made it less likely that these items would continue to cross-load in the short-
 44 form.

45
 46 To assess the validity of the short-form scales, we correlated them with the full scales derived

1 from factor analysis, as well as those presented by Scheirs and Sijtsma (2001). All three short-
 2 form scales correlated with both versions of their longer counterpart $>.90$, suggesting that they
 3 adequately capture each factor (see Table 3). Cronbach's alphas for the short-form subscales
 4 were $>.80$ and females scored significantly higher than males on all three subscales (see Table
 5 3).

7 **Confirmatory factor analysis (Sample 2)**

8 **Attitudes toward crying.** We performed a confirmatory factor analysis on the short-form
 9 attitudes scale using SPSS AMOS 22. We modeled all 13 items as loading only onto their
 10 respective factors and allowed all four factors (i.e., Feels better, Healthy, Hatred, and Control) to
 11 covary freely. Due to missing data on several items we used Full Information Maximum
 12 Likelihood estimation. We evaluated model fit using a range of recommended indices (Hu &
 13 Bentler, 1999). These were χ^2 (which tests the null hypothesis that the model does not differ
 14 significantly from the data, but is highly sensitive to sample size so rarely nonsignificant; Bollen,
 15 1989); normed- χ^2 (i.e., χ^2 divided by df to reduce influence of sample size: good if ≤ 2 ; Ullman,
 16 2001); comparative fit index (CFI: good if $\geq .95$, acceptable if $\geq .90$; Brown, 2006); and root-
 17 mean-square error approximation (RMSEA: good if $\leq .06$, adequate if $\leq .08$; Brown, 2006).
 18 When comparing fit of nested models, we used the significance level of $\Delta\chi^2$ and a critical value
 19 of $\Delta CFI = .010$ compared to the reference model (Byrne, 2010; Cheung & Rensvold, 2002).
 20 When comparing the fit of non-nested models, we used the Akaike Information Criterion (AIC;
 21 smaller values indicate better fit; Akaike, 1987; Brown, 2006).

22
 23 The model fit was adequate and met criteria for acceptable fit, $\chi^2(59) = 274.61$, normed- $\chi^2 =$
 24 4.65, CFI = .942, RMSEA = .068, AIC=364.61. All items loaded significantly onto their
 25 respective factors, $\beta_s > .467$, $ps < .001$. As shown in Figure 1, the factors were moderately
 26 correlated, with the exception of Healthy and Feels Better, which were strongly correlated.
 27 However, an alternative model in which these two factors were combined into one showed
 28 reduced fit, $\Delta\chi^2(1) = 87.54$, $p < .001$, $\Delta CFI = .024$, $\Delta AIC = 85.54$.¹

29
 30 **Crying proneness.** Next, we performed a confirmatory factor analysis on the crying proneness
 31 scale using the same principles as above to model the three correlated factors (i.e., Threat to Self,
 32 Sadness, and Joy). Using Full Information Maximum Likelihood estimation in the full sample,
 33 the model fit acceptably but not excellently, $\chi^2(132) = 732.95$, normed- $\chi^2 = 5.55$, CFI = .923,
 34 RMSEA = .076, AIC = 846.95. All items loaded significantly onto their respective factors, $\beta_s >$
 35 $.57$, $ps < .001$. A supplementary model in which we included only participants with complete
 36 data in order to obtain Modification Indices ($n = 725$) did not identify any substantial and
 37 theoretically sensible cross-loadings or error covariances, so we retained the model (Figure 2).
 38 The factors were moderately to highly correlated. However, an alternative model in which Threat
 39 to Self and Sadness were combined into one factor (i.e., conceptually modeling crying in positive
 40 vs. negative contexts) showed reduced fit, $\Delta\chi^2(1) = 52.84$, $p < .001$, $\Delta CFI = .007$, $\Delta AIC =$
 41 50.84.²

42
 43
 44 **Do attitudes towards crying mediate attachment differences in crying proneness?** Having
 45 established the factor structure of both the proneness and attitudes components of the ACI, we
 46 then sought to test our hypotheses that attitudes towards crying would mediate the relationship

1 between attachment and crying proneness (Figure 1). We began by examining the relationships
2 between attachment, attitudes, and crying proneness (see Table 4). In Sample 1, attachment
3 avoidance correlated negatively with sadness crying proneness, and correlated negatively with
4 the attitudes that crying Feels Better and is Healthy, and positively with Hatred and Control.
5 Attachment anxiety correlated positively with all three forms of crying proneness, and with the
6 attitudes that crying Feels Better, is Healthy, and Hatred, but negatively with Control. In
7 addition, all three crying proneness variables correlated positively with the attitudes that crying
8 Feels Better and is Healthy, and negatively with Hatred and Control.

9
10 Having broadly found support for each of the proposed pathways in our conceptual model
11 (Figure 3), we proceeded to conduct the multiple mediation models. We first tested our model
12 with Sample 1, and subsequently examined the extent to which we could replicate it in Sample 2,
13 using the short form subscales in both cases. We used SPSS PROCESS (Hayes, 2013) to
14 examine each of the three crying proneness dependent variables in turn. In each analysis,
15 attachment avoidance (controlling for anxiety) or attachment anxiety (controlling for avoidance)
16 was the predictor variable, and all four attitudes towards crying were entered as the mediators. In
17 reporting results, we use terms such as “effect” and “explain” in a statistical sense only,
18 acknowledging the correlational nature of our data.

19
20 **Sample 1.** In preliminary analyses, we first included gender as a moderator, allowing us to test
21 for gender interactions in both the direct and indirect (mediated) effects. Only one significant
22 gender moderation occurred, on the direct effect of anxiety on crying through sadness ($B = -.20$,
23 $p < .05$), indicating that attachment anxiety was a significant positive predictor of crying through
24 sadness for men but not for women. Because this represented a single significant interaction
25 effect out of a possible 30 (6 direct and 24 indirect), and because our primary focus was the
26 indirect rather than main effects (which have already been established to some extent by Denckla
27 et al., 2014; Laan et al., 2012; and, Bartholomew and Horowitz, 1991), in the interests of
28 obtaining the most parsimonious models, we opted to re-run our analyses controlling for gender
29 rather than treating it as a moderator. Direct and indirect effects are displayed in Table 5, and
30 individual coefficients are displayed in Figure 4.

31
32 Controlling for anxiety, avoidance had a significant, positive, direct effect on crying from joy.
33 Crucially, and consistent with our hypotheses, avoidance had significant indirect (mediated)
34 negative effects via the attitudes crying is healthy, and crying is controllable, on all three
35 proneness factors (threat to self, sadness, and joy). That is, highly-avoidant (vs. low-avoidant)
36 individuals' beliefs that crying is not healthy and that they can control their tears, explains their
37 low proneness to crying. Additionally, avoidance had an indirect, positive effect on crying
38 through threat to self via the attitude that crying is hated. The indirect effect is in the opposite
39 direction to the zero-order correlation between hatred and crying through threat to self, implying
40 a possible suppression pattern. Because hatred and control are correlated, when partialing out the
41 attitude that crying is controllable, avoidant individuals' hatred of crying ironically relates to
42 *increased* tendency to cry when feeling threatened. A similar pattern may explain the direct
43 positive effect of avoidance on crying through joy, when controlling for the negative indirect
44 effects described above. However, we interpret these unexpected findings with caution,
45 especially given the notorious difficulty in replicating suppression effects (Paulhus, Robins,
46 Trzesniewski, & Tracy, 2004).

1
2 Controlling for avoidance, anxiety had direct, positive effects on crying through threat to self and
3 sadness. Consistent with hypotheses, anxiety also had indirect positive effects on all three
4 proneness factors via the attitudes crying is healthy, and crying is controllable. Additionally,
5 anxiety had an indirect, positive effect on crying through threat to self via the attitude that crying
6 is hated. That is, highly-anxious (vs. low-anxious) individuals' beliefs that crying is healthy and
7 that they cannot control their tears, partly explain their higher proneness to crying. In addition, a
8 suppression effect implies that, like avoidant individuals, anxious individuals' hatred of crying is
9 associated with greater crying proneness when experiencing threat to self.

10
11 In Sample 1 we have demonstrated for the first time that the relationship between attachment and
12 crying is mediated by attitudes towards crying. Strikingly, for both attachment dimensions, the
13 attitudes that crying is healthy and crying is controllable were significant mediators across all
14 three proneness factors. That is, avoidant individuals' lower proneness, and anxious individuals'
15 higher proneness to crying, are partly explained by their relative beliefs in the healthiness and
16 controllability of tears. Further, hatred of crying showed a suppression pattern, possibly implying
17 that this attitude ironically related to greater proneness to crying through threat to self for
18 insecure individuals. The attitude that crying helps one to feel better was not a significant
19 mediator in any model. Residual direct effects for both avoidance and anxiety on crying through
20 sadness, and anxiety on crying through threat to self, indicate that other mechanisms may also
21 play a role in explaining attachment differences in crying. We sought to replicate these findings
22 in Sample 2.

23
24 **Sample 2.** Similar to Sample 1, the correlations for Sample 2 (Table 4) showed that attachment
25 avoidance correlated negatively, and attachment anxiety positively, with all three crying
26 proneness factors. We therefore proceeded to test multiple mediation models in the same way as
27 with Sample 1 (Table 5). Similar to our first sample, in Sample 2, the attitudes Healthy and
28 Control consistently mediated between attachment and crying proneness in all three contexts.
29 That is, once again individuals higher (vs. lower) in avoidance reported less proneness to crying.
30 —and this was partly explained by their beliefs that crying is unhealthy and can be controlled.
31 Those higher (vs. lower) in anxiety held the opposite attitudes, and this partly explained their
32 higher proneness to crying.

33
34 However, Sample 2 also yielded some different findings from Sample 1. First, in Sample 2 we
35 found that the attitude Feels Better significantly mediated the links between both avoidance and
36 anxiety and crying through sadness and joy (alongside the two replicated mediators described
37 above). Second, hatred also mediated the effect of avoidance on crying through joy, but did not
38 mediate or suppress effects on threat to self (unlike Sample 1). Finally, Sample 2 showed more
39 direct effects. As well as replicating the direct effects of both avoidance and anxiety on crying
40 through sadness, and of anxiety on crying through threat to self, Sample 2 also showed a direct
41 effect of avoidance on crying through threat to self, and anxiety on crying through joy.

42
43 **The role of gender.** Supplementary analyses using PROCESS model 8 (Hayes, 2013) examined
44 whether gender moderated the above results in Sample 2. Significant interactions were observed
45 for two direct effects and eight indirect effects. In the case of one direct effect (i.e., anxiety on
46 threat to self), the coefficient was significant for both genders but stronger for women. In the

1 case of three indirect effects (i.e., indirect effects of anxiety via Feels Better), coefficients were
 2 significant for both genders but stronger for men—in fact, all the same indirect paths were
 3 significant for men's and women's anxiety. For the remaining six effects (all concerning
 4 avoidance), the coefficient was significant for women but non-significant for men—in fact no
 5 indirect effects were significant for men's avoidance. The remaining 20 paths were not
 6 moderated by gender. Overall, attachment anxiety and its incumbent attitudes play an equal if not
 7 stronger role for men (compared to women), but attachment avoidance and its incumbent
 8 attitudes to crying appear to play a lesser role in crying proneness for men (compared to women).
 9 Sex differences in adult attachment orientations and behaviors are relatively uncommon (J. A.
 10 Feeney & Noller, 1996) but our results indicate that they exist with regards to crying (see also
 11 Frey, 1985). These findings are congruent with research showing that for men, unlike women,
 12 attachment avoidance is not a reliable predictor of support seeking behavior, of which crying is
 13 an extreme form (Simpson, Rholes, Oriña, & Grich, 2002). It has been speculated that such
 14 findings may be explained by sex roles differentially affecting the link between attachment
 15 orientations and coping with stress (Shaver et al., 1996), such that attachment system activation
 16 has a higher threshold in men, may be particularly true for high avoidant men.

17
 18 ***Do attachment and attitudes toward crying predict most recent crying episode?*** In Sample 2,
 19 we additionally asked participants about their most recent crying episode. We used Spearman's
 20 rho to examine correlations with the ordinal-scale reports of participants' most recent crying
 21 episode (Table 4). Women (vs. men), and those higher (vs. lower) in attachment anxiety reported
 22 having cried more recently, for longer duration, and more intensely. Attachment avoidance
 23 correlated only with having cried less recently. Recent episode reports also correlated weakly to
 24 moderately with overall crying proneness and crying attitudes. We again used PROCESS to
 25 examine indirect effects of attachment on most recent crying episode via attitudes toward crying,
 26 controlling for age and sex³. Direct and indirect effects are displayed in Table 6, and individual
 27 coefficients are displayed in Figure 5.

28
 29 Overall, attachment and attitudes variables explained a statistically significant, but modest,
 30 proportion of variance in characteristics of most recent crying episode. The attitudes Healthy and
 31 Control mediated the links between both attachment dimensions and recency of crying episode.
 32 These results conceptually replicate the above-reported indirect effects for the crying proneness
 33 scale, using a more indirect and relatively implicit indicator of crying proneness. Anxiety
 34 showed direct effects on duration and intensity of crying and also indirect effects via Control.
 35 High-anxious individuals cry more intensely and are less able to stop, partly explained by their
 36 relative lack of control over crying. For avoidance, despite non-significant raw correlations, there
 37 were significant indirect effects on duration and intensity of crying via Control. High-avoidant
 38 individuals' perceived greater control related to slightly less intense and shorter crying episodes.
 39 Interestingly, avoidance also yielded a significant and positive indirect effect on intensity of
 40 crying via Hatred. Conceptually replicating the finding in Sample 1 for crying proneness, high-
 41 avoidant individuals' hatred of crying (after partialing out other attitudes) is ironically associated
 42 with their crying episodes being more intense.

43
 44 Finally, supplementary analyses tested the moderating effects of sex. Significant interactions
 45 were observed for one direct effect (i.e., anxiety on recency) and four indirect effects (i.e., effects
 46 of avoidance on all three outcomes via Control, and on intensity via Hatred). In all five cases, the

1 coefficient was significant for women but not for men—a similar pattern as observed for crying
2 proneness outcomes in Sample 2. The remaining 25 effects, including five significant effects of
3 anxiety and one significant effect of avoidance, were not moderated by gender.

4 5 **General discussion**

6
7 In two large samples, we have identified factor structures for the proneness and attitudes
8 components of the ACI, and recommended short forms to aid future utility. We have also
9 delineated attitudes as a possible mechanism of the previously reported relationship between
10 attachment orientation and crying proneness (Denckla et al., 2014; Laan et al., 2012). Our
11 findings therefore have both theoretical and practical implications.

12
13 **Theoretical implications.** We have reliably shown that the relationship between adult
14 attachment orientation and crying proneness is partially mediated by attitudes towards crying.
15 While there were some differences between the two sets of results, a core set of findings was
16 replicated across both studies: the direct, positive effects of anxiety on crying through threat to
17 self, and on crying through sadness; and indirect effects of both avoidance and anxiety on all
18 three forms of proneness via the attitudes that crying is healthy and controllable. We discuss
19 these in turn.

20
21 We replicate and extend the previously reported relationship between attachment and crying
22 proneness (Bartholomew & Horowitz, 1991; Laan et al., 2012), in two samples, with the
23 additional contribution that attitudes are an important mechanism of this relationship. Firstly, in
24 both samples, we found evidence of a direct effect of attachment anxiety on crying due to threat
25 to self and sadness, but not joy. Individuals with higher (vs low) levels of attachment anxiety
26 were more likely to cry for negative reasons. This finding is in keeping with previous literature,
27 where those high in anxiety reported greater propensity for vicarious crying (for reasons such as
28 attachment-related life events, society, sentimentality, and compassion, Denckla et al., 2014),
29 and crying for negative rather than positive reasons (Laan et al., 2012). We further found that
30 individuals with higher (vs. lower) anxiety reported crying more recently (further replicating
31 their tendency to cry frequently) and that their most recent crying episode lasted longer. Because
32 attachment anxiety reflects a hyperactivating affect regulation strategy (Mikulincer & Shaver,
33 2007), experiences and responses to threat and negative emotions are exaggerated in high
34 anxious individuals. The proneness to crying observed in highly anxious individuals may be due
35 to them perceiving threats more readily (Baldwin & Kay, 2003; Fraley, Niedenthal, Marks,
36 Brumbaugh, & Vicary, 2006) and experiencing negative emotions more keenly, leading these
37 individuals to intensify their emotions (Mikulincer & Shaver, 2007). This intensification also
38 accounts for the longer duration of high-anxious individuals' crying episodes, as they struggle to
39 regulate and alleviate negative affect.

40
41 Secondly, and most importantly, we found that the attitudes crying is healthy and can be
42 controlled mediated relationships between both attachment dimensions and all three crying
43 proneness factors in both samples, as well as the recency of the last crying episode (in Sample 2).
44 Attachment avoidance was negatively related to the attitude that crying is healthy, which partly
45 explained avoidant individuals' low proneness to crying through threat to self, sadness, and joy,
46 and less-recent crying episodes. Given that crying is an attachment behavior designed to elicit

1 support and care from others (Nelson, 2005), avoidant individuals likely perceive it as an
2 unwelcome emotional display and a sign of weakness that undermines their self-reliance
3 (Cassidy, 1994). Indeed, research has found that mothers classified 'dismissing-avoidant' on the
4 adult attachment interview (George, Kaplan, & Main, 1996) show activation of the anterior
5 insular when presented with images of their own infants crying (Strathearn, Fonagy, Amico, &
6 Montague, 2009) - an area associated with aversive feelings such as disgust, unfairness, and pain
7 (Montague & Lohrenz, 2007). Our finding that avoidant individuals report hatred of crying
8 further supports this notion. Further research might examine the neural correlates of aversiveness
9 of own crying.

10
11 Attachment avoidance was also positively related to the attitude that crying is controllable,
12 perhaps because avoidance is essentially a deactivating affect regulation strategy. This sense of
13 control also partly explained avoidant individuals' low proneness to crying through threat to self,
14 sadness, and joy, and less-recent crying episodes. Avoidant individuals inhibit and suppress their
15 emotional experience (Wei, Vogel, Ku, & Zakalik, 2005) and may find it (relatively) easy to
16 avoid crying. Indeed, research has found that avoidant individuals are capable of suppressing the
17 activation of their attachment system (Fraley & Shaver, 1997). The finding that beliefs about the
18 controllability of crying explained their lower crying proneness is also in keeping with previous
19 research; Spokas et al. (2009) found that attitudes regarding the importance of controlling
20 emotional expression reduced emotional expression.

21
22 Attachment anxiety had a positive effect on the attitude that crying is healthy, which partly
23 explained anxious individuals' relatively high proneness to crying through threat to self, sadness,
24 and joy. Because anxious individuals, driven by unsatisfied needs for care and support, engage in
25 hyperactivation of threat related negative emotions in a bid to seek support from caregivers
26 (Cassidy, 1994), it follows that they would view crying positively. For high-anxious individuals
27 crying may appear a healthy thing to do because it fits with their emotion-focused and support-
28 seeking coping strategies (Mikulincer & Shaver, 2007).

29
30 Attachment anxiety related negatively to the attitude that crying is controllable, which also partly
31 explained anxious individuals' proneness to crying through threat to self, sadness, and joy - as
32 well as greater recency, duration and intensity of the most recent crying episode. Those high in
33 attachment anxiety are emotionally reactive to external stimuli (Wei et al., 2005) and may
34 experience spreading activation of negative affect, due to neural pathways defined by experience
35 favouring hyperactivation rather than down-regulation. Gillath, Bunge, Shaver, Wendelken, and
36 Mikulincer (2005) found that attachment anxiety was positively associated with activation in the
37 anterior temporal pole, which is linked with sadness, and negatively associated with activation in
38 the orbitofrontal cortex, which is linked with emotion regulation, among participants asked to
39 think about, and then stop thinking about negative relationship scenarios. When those high in
40 anxiety experience sufficient cause to cry through sadness, it might be that that these same brain
41 areas are responsible for their (in)ability to down-regulate sufficiently to control or prevent
42 themselves from crying.

43
44 In addition to these consistent and robust findings, some effects were statistically significant in
45 only one of our two samples. However, in all cases, the direction of the coefficients was
46 consistent across both samples. In Sample 2 (but not in Sample 1), the attitude that crying makes

1 one feel better significantly mediated the relationships between both avoidance and anxiety and
2 crying through sadness and joy. That is, in both samples avoidance was negatively related to the
3 attitude that crying makes one feel better, but only in Sample 2 did this explain additional
4 variance in avoidant individuals' low crying through sadness and joy. Avoidant individuals have
5 learned that there is little point in expressing negative emotions because no assistance with their
6 downregulation is forthcoming (Cassidy, 1994). It therefore follows that they would perceive
7 that crying would not make them feel better. Anxiety was positively related to the attitude that
8 crying makes one feel better in both samples, and in Sample 2 this explained additional variance
9 in anxious individuals' high crying through sadness and joy. This is likely to be linked to anxious
10 individuals' tendency to perceive the expression of negative emotions as a means of securing
11 access to the support of an attachment figure (Cassidy, 1994). The emergence of these additional
12 effects in Sample 2 might reflect greater statistical power.

13
14 Additionally, hatred of crying played interesting but inconsistent roles. In Sample 1 (but not in
15 Sample 2), significant indirect effects via hatred of crying were obtained for the links of both
16 avoidance and anxiety with crying through threat to self. Furthermore, in Sample 2, a significant
17 indirect effect via hatred was obtained for the link between avoidance and intensity of most
18 recent episode. Both avoidance effects indicated a possible suppression pattern: high avoidance
19 was associated with greater hatred of crying, which in turn was associated with a *greater*
20 likelihood of crying through threat to self and *greater* intensity of recent crying. The conceptual
21 replication of this finding across samples implies that it might warrant further attention. While it
22 may be counter-intuitive that greater hatred of crying rendered avoidant individuals more likely
23 to cry and to do so more intensely, this is likely because hatred of crying was highly correlated
24 with the attitude that crying is controllable (which was also included in the mediation models).
25 The positive effect of hatred of crying on crying (through threat to self) is what remains after
26 accounting for the view that crying can be controlled. Thus, highly avoidant individuals' hatred
27 of crying relates to a higher propensity to cry, but this is countered by their sense of control.
28 Finally, in Sample 2, hatred of crying more straightforwardly mediated the negative association
29 between avoidance and crying through joy. Thus, the ironic effect of high-avoidants' hatred on
30 increased crying appears specific to episodes in which they feel threatened or are already crying -
31 that is, when their defences are low, perhaps because their general affect regulation strategy of
32 deactivation fails under increased load (Mikulincer, Birnbaum, Woddis, & Nachmias, 2000).

33
34 These findings have implications for interpersonal and intrapersonal functioning. Crying conveys
35 important information to attachment figures. Avoidant individuals, who believe that crying is
36 unhealthy but controllable, may rarely cry in front of their romantic partners in upsetting
37 situations, giving their partners little information about their emotional state, perhaps at times at
38 which a partner might expect to see emotions expressed. Conversely, anxious individuals, who
39 believe that crying is healthy but uncontrollable, are likely to cry more frequently and with more
40 ease in front of their partners, providing their partners with plenty of information about their
41 emotional state. Such individuals may be hampered in their ability to respond to their partner
42 crying because their own emotional reactions get in the way (B. C. Feeney & Collins, 2001).
43 Further research should examine the interpersonal effects of different attitudes towards crying in
44 the context of close relationships and build on work showing individual differences in implicit
45 reactions to others' crying (Lockwood, Millings, Hepper, & Rowe, 2013).

1 Attitudes about one's own crying also have implications for intrapersonal functioning. Crying is
2 generally hard to control (Vingerhoets & Cornelius, 2001), and particularly so in situations of
3 extreme stress or threat. For an individual high in attachment avoidance it may be disturbing to
4 find that emotions can and will sometimes overtake one and result in crying. This mismatch
5 between expectations and reality is likely to result in cognitive dissonance (Festinger, 1957) and
6 may have negative psychological consequences.

7
8 **Practical implications.** We proposed and tested short form versions of the Adult Crying
9 Inventory's (Vingerhoets, 2001, in Vingerhoets & Cornelius, 2001) attitudes towards crying and
10 crying proneness dimensions. We obtained a very similar factor structure for crying proneness to
11 those reported previously (Scheirs & Sijtsma, 2001), and proposed a shortened version of this
12 scale, reducing 55 items down to a much more user-friendly 18 items that fit the data in CFA.
13 The subscales of the short form possess good alphas and correlate very highly with the long
14 form, meaning that future researchers can be confident that the short form adequately captures
15 the nuances of crying proneness covered in the long form.

16
17 We also produced a factor structure for the attitudes towards crying scale, comprising the
18 attitudes that crying helps one feel better, crying is healthy, crying is hated, and crying can be
19 controlled. To the best of our knowledge, this is the first time a factor structure for this aspect of
20 the ACI has been reported. We also propose a shortened version of this scale, reducing 24 items
21 down to 13, which fit the data in CFA. The correlations between short and long form factors
22 were high, and the alphas for three of the four subscales were good. We therefore recommend
23 expansion of the fourth, Control subscale, which in our short form contained only 2 items.

24
25 **Limitations and implications for future research.** Despite replicating our key findings across
26 two samples, the largest methodological limitation is the cross-sectional nature of their designs.
27 Having highlighted attitudinal mediators in the relationship between attachment orientation and
28 crying, further research is required to establish whether these effects are causal, both in the short
29 term and in the longer term. This could be achieved using diary and longitudinal studies,
30 respectively. A further limitation is the self-report nature of our work, which may result in
31 monomethod bias, as well as demand characteristics. Future research could overcome these
32 issues by triangulating self and close other reports, or using stimuli likely to cause crying in the
33 lab (e.g. Cornelius, 1997).

34
35 **Conclusion.** We investigated the roles of attachment orientation and attitudes towards crying, in
36 everyday crying proneness. We found that attitudes towards crying, specifically the attitudes that
37 crying is healthy and that crying is controllable, reliably explain attachment orientation
38 differences in crying proneness in situations involving threat to self, sadness, and joy, as well as
39 the strength of specific crying episodes. While high avoidant individuals reported believing that
40 crying was both unhealthy and controllable, high anxious individuals reported believing that
41 crying was a healthy behavior, but one that they could not control. For individuals high on either
42 attachment dimensions, these beliefs played a pivotal role in their crying proneness and most
43 recent crying experiences. Our results extend the literature on adult attachment and crying in
44 theoretically meaningful and interpretable ways. We have also proposed shortened versions of
45 both the ACI attitudes towards crying and proneness to crying scales, offering future researchers
46 briefer tools with which to study the emotional expression process of crying.

47

Footnotes

¹We tested whether the four-factor attitudes model fit equivalently for both women and men. First, we tested for configural invariance by fitting the model separately in each sex group. Both models fit adequately, but in the male sample one error variance estimate was negative (item 23: "I hate to cry"), rendering the solution inadmissible. Such a Heywood case can indicate insufficient indicators per latent variable (Westland, 2015) and so likely reflects the presence of only two indicators for Control. Thus, we fixed this error variance to 0.01 in the male sample analysis. The model fit adequately for both women, $\chi^2(59) = 192.83$, $\chi^2/df = 3.27$, CFI = .946, RMSEA = .063, and men, $\chi^2(60) = 134.87$, $\chi^2/df = 2.25$, CFI = .924, RMSEA = .078, with all factor loadings significant ($\beta_s > .42$).

Subsequently, we tested a multiple-group CFA model and imposed sequential constraints to examine between-group invariance in the measurement and structural model (Byrne, 2010). To avoid the inadmissible solution in the male sample, we constrained the relevant error variance equal across sexes (Westland, 2015). This model fit adequately, $\chi^2(119) = 330.40$, $\chi^2/df = 2.78$, CFI = .939, RMSEA = .048. To test structural invariance, we: (i) constrained item loadings to be equal across sexes, then (ii) further constrained covariances between factors to be equal (while fixing latent means to 0). The constrained model did not fit significantly worse than the unconstrained model, $\Delta\chi^2(15) = 16.51$, $p = .35$, $\Delta CFI = .00$. Thus, the same factor structure fits the attitudes scale in women and men.

Finally, we tested scalar invariance (i.e., equivalence of item intercepts), which would indicate that a person with the same underlying level of the latent factor would obtain the same score on each item regardless of their sex. We fixed the four latent means for men to 0 but allowed the means for women to vary, and constrained item intercepts to be equal. This model fit less well than the structural invariance model, $\Delta AIC = 54.32$, implying that given the same underlying level of crying attitude, men and women report different attitudes on the scale. Inspection of individual items revealed that the intercepts were significantly different for 11/13 items (Z s ranging from $|3.16-10.09|$), all reflecting women's (vs. men's) greater willingness to endorse pro-crying items, and lesser willingness to endorse anti-crying items. This pattern likely reflects social desirability response bias. Nevertheless, the factor structure of the scale was equivalent across sexes.

²We tested for equivalence of the model across sexes in the same way as for the attitudes scale. First, we established that the model fit adequately, though no better than the overall model, in each sex group separately; women: $\chi^2(132) = 548.34$, normed $\chi^2 = 4.15$, CFI = .896, RMSEA = .074; men: $\chi^2(132) = 325.74$, normed $\chi^2 = 2.47$, CFI = .907, RMSEA = .084. Then, we followed the same multiple-group CFA procedure as for the attitudes scale to test for measurement, structural, and scalar invariance. The unconstrained model fit reasonably, $\chi^2(264) = 874.37$, normed $\chi^2 = 2.47$, CFI = .900, RMSEA = .055. Constraining the item loadings and factor covariances equal across sexes did not reduce model fit substantially, $\Delta\chi^2(18) = 38.38$, $p = .003$, $\Delta CFI = .004$, and no individual parameters differed between sexes at $p < .001$. Thus, the same factor structure fits the crying proneness scale for both women and men. However, again the scalar invariance model (with equal intercepts) fit less well than the structural invariance model, $\Delta AIC = 70.58$. Every item intercept differed between sexes (Z s = 3.05-17.85), all reflecting women's greater willingness to endorse crying proneness items. Again we note the likely influence of social desirability bias but emphasize the equivalent factor structure.

³Although PROCESS is not designed for use with ordinal dependent variables, we note that supplementary ordinal regressions obtained the same pattern of direct effects as those

1 reported (but cannot test indirect effects). In addition, bootstrapping tests of indirect effects do
2 not rely on parametric assumptions, meaning that the mediation tests are valid and lending
3 further confidence to our conclusions.

12 **Author Contributions**

13
14 The research was designed by all the authors jointly. Sample 1 was collected by AM and AR.
15 Sample 2 was collected by EH and CH. Statistical analyses were undertaken by AM, LS, EH,
16 and CH. All the authors contributed to and approved the final manuscript, coordinated by AM.
17

18 **Funding**

19
20 This research was supported by grants from the Economic and Social Research Council. Grant
21 number ES/F030215/1 supported data collection and grant number ES/L001365/1 supported
22 manuscript preparation.
23

24 **Conflict of Interest Statement**

25
26 The authors declare that the research was conducted in the absence of any commercial or
27 financial relationships that could be construed as a potential conflict of interest.

Table 1: *Exploratory factor analysis loadings for attitudes towards crying (Sample 1)*

Items	Factor			
	1 Feel Better	2 Healthy	3 Hatred	4 Control
10. I feel relaxed after a good cry	.830	.007	-.027	.035
12. After a good crying spell I am more optimistic about the future	.802	-.058	.014	.084
15. I feel peaceful after a good cry	.791	.087	.042	-.190
9. I find that I feel better after a good cry	.779	.013	-.077	.085
11. After a good crying spell I am able to cope with my problems	.752	-.004	.034	.171
14. After crying I feel warm all over	.576	.201	.175	-.143
8. If I let myself cry deeply, I sleep better	.412	.125	.063	.333
5. Crying is an important and effective way of dealing with life's difficulties	-.084	.979	.003	-.159
3. My life would be better if I were able to really have a good cry	.092	.728	.041	-.111
16. Crying is the healthiest thing you can do when you are feeling sad	.105	.728	.009	-.157
4. I use crying to help me feel better, when I have problems	.069	.631	-.038	.159
2. I believe that it is useful to cry when life becomes stressful	.132	.597	-.020	.129
1. Crying helps me to deal with my problems	.097	.502	-.095	.179
21. I like to cry	.076	.432	-.326	.013
6. I would rather cry about a problem than keep all my sadness inside	.044	.403	-.201	.284
17. When I am not able to cry in a stressful situation I stay feeling tense	.162	.367	.133	.251
23. I hate to cry	.006	-.094	.734	-.039
19. I feel ashamed when I am crying	.061	.033	.723	.141
13. I try not to cry when I am upset	.192	-.145	.578	-.136
20. After crying I feel often more miserable than before	-.468	.215	.529	.328
7. Under certain conditions, when things are bad, I have cried almost uncontrollably	.015	-.139	.056	.824
18. Mostly I can control my tears	.170	.164	.287	-.542
24. I can manipulate others with my tears	-.021	.006	.051	.313
22. Other people generally become gentler when I cry	.077	.031	.175	.289

Note: Items in bold comprise our recommended short form subscales. Item 7 is reversed in the short form.

Table 2: Exploratory factor analysis loadings for crying proneness (Sample 1) compared to Scheirs & Sijtsma's (2001) study

Items	Sample 1 FA			S & S (2001)
	Threat to Self	Joy	Sadness	
24. ...having been humiliated/insulted	.926	-.039	-.101	F1
35. ...when things don't go as I want them to	.875	-.076	-.034	F1
41. ...when I am in a blind-alley situation	.817	.022	-.011	F1
34. ...when feeling self pity	.801	-.049	-.063	F1
23. ...when I feel powerless	.790	.135	-.178	F1
32. ...when someone criticizes or lectures me	.775	-.043	.004	F1
28. ...when I experience opposition from someone else	.769	.149	-.173	F1
36. ...when I feel guilty	.757	.036	-.050	F1
40. ...when I feel rejected by others	.736	-.066	.149	F1
9. ...when I do not succeed in getting things together	.726	.033	.066	F1
39. ...when I am in despair	.716	.013	.109	F1
12. ...when things do not go well with work/studies	.685	-.012	.121	F1
29. ...when I feel frightened	.662	-.051	.136	F1
5. ...when I feel ashamed	.657	.026	.027	F1
30. ...when I feel angry	.651	.017	.051	F1
19. ...when involved in quarrels/conflicts	.650	-.074	.190	F1
10. ...when I experience disgust or contempt for something/one	.550	.237	-.198	F1
49. ...when I realise my own vulnerability/mortality	.479	.177	.067	F1
44. ...when I am ill	.457	-.047	.277	F1
6. ...deliberately to make someone feel sorry for me	.416	.053	-.012	F1
37. ...out of pity for others	.298	.278	.179	F2
27. ...in response to beauty of arts	.004	.766	-.106	F3
54. ...when watching/hearing an admired person	.005	.719	.002	F3
33. ...when watching awards ceremony at sporting event	-.134	.656	-.038	F3
14. ...when I hear a happy song	-.039	.637	.039	F3
3. I can be moved to tears by beauty of natural scenes	.001	.625	.037	F3
47. ...when I hear national anthem or see national flag rise	-.111	.610	-.146	F3
22. ...while reading poetry	.167	.607	-.183	F3
55. ...when I have achieved success	.124	.474	.090	F3
46. ...when practicing religious activities	.120	.440	-.213	F3
15. ...when someone does something very special for me/someone	-.030	.440	.410	F3
18. ...happy memories	.131	.439	.156	F3
11. ...when I feel very happy	-.117	.420	.339	F3

20. ...at weddings	-.036	.418	.337	F3
4. ...when making love	.195	.358	-.109	F3
52. ...when I am reuniting with friends/family members	.200	.340	.235	F3
25. ...when reading certain books	.137	.335	.259	F2
17. ...because of problems of someone else	.247	.319	.237	F2
7. ...when feel relief	.287	.300	.143	F3
43. ...when talking with therapist/doctor	.195	.234	.099	F1
45. ...while I watch sad film/TV	-.189	.137	.834	F2
31. ...when a tragic event happens	.236	-.365	.788	F2
26. ...at funerals	.011	-.136	.731	F2
2. ...when I say goodbye to loved ones	.190	-.033	.588	F2
1. ...when I feel sad	.336	-.088	.506	F2
8. ...over loss of love relationship	.296	-.217	.496	F2
16. ...if I remember sad things that happened to me	.269	-.009	.491	F2
13. ...film/TV happy ending	-.230	.445	.482	F3
38. ...when I experience physical pain	.399	-.194	.460	F1
50. ...when I see others suffering	.181	.225	.446	F2
48. ...when I experience painful memories	.387	-.047	.420	F2
51. ...when I attend/witness memorial meetings	.058	.239	.391	F3
21. ...when I hear a sad song	.143	.300	.380	F2
42. Sometimes I laugh so hard I cry	-.074	.083	.366	
53. ...when I watch other people crying	.312	.152	.362	F2

Note: S & S = Schiers & Sijtsma (2001). All items (except 3 and 42) are prefaced with 'I cry' and some are truncated. Items in bold comprise our recommended short form subscales. Item 42 does not appear in Scheirs & Sijtsma's (2001) analysis, but does appear in the appendix presenting the inventory items, and therefore was included in our analyses.

Table 3: *Sample 1 Means, SDs, and independent samples t-tests for short form attitudes and proneness subscales by gender*

	Cronbach's alpha	Men <i>M</i> (SD)	Women <i>M</i> (SD)	<i>t</i>	<i>df</i>	Effect size ^a	Correlation with long form (derived from our FA)	Correlation with long form (Scheirs & Sijtsma, 2001)

<i>Proneness</i>								
Threat	.91	2.02 (1.03)	3.93 (1.22)	19.92**	517.31	1.66	.96*	F1 .95*
Joy	.83	1.83 (.92)	2.83 (1.12)	-11.68**	527.25	.97	.93*	F3 .94*
Sadness	.87	2.94 (1.24)	4.77 (1.01)	-18.08**	397.33	1.65	.96*	F2 .96*

Note: ** $p < .001$, * $p < .05$. ^aHedges *g* was used due to uneven sample sizes.

Table 4: Correlations between key study variables in both samples

	Attachment		Attitudes to Crying				Crying Proneness			Demographics	
	Avoidance	Anxiety	Feels Better	Crying is healthy	Hatred	Control	Threat to Self	Joy	Sadness	Age	Sex
Attachment avoidance	—	.20	-.20	-.22	.31	.13	-.05	-.01	-.17	-.07	-.04
Attachment anxiety	.08	—	.16	.18	.17	-.25	.37	.17	.25	-.18	.16
Attitude: Feels Better	-.13	.21	—	.68	-.39	-.31	.37	.31	.42	-.04	.28
Attitude: Crying is healthy	-.19	-.25	.71	—	-.39	-.36	.48	.39	.53	-.01	.39
Attitude: Hatred to cry	.32	.07	-.26	-.27	—	.22	-.09	-.18	-.23	-.08	-.16
Attitude: Control	.17	-.30	-.32	-.33	.18	—	-.56	-.34	-.55	.12	-.52
Prone: Threat to Self	-.15	.43	.41	.45	-.12	-.57	—	.51	.73	-.21	.63
Prone: Joy	-.15	.19	.44	.42	-.23	-.33	.51	—	.64	.08	.40
Prone: Sadness	-.24	.30	.48	.50	-.23	-.51	.75	.62	—	-.05	.63
Age (log transformed)	.02	-.16	-.05	-.05	-.02	.08	-.09	.13	-.01	—	-.15
Sex	-.09	.11	.24	.22	-.11	-.38	.51	.28	.57	-.05	—
Recent episode: Recency ^a	-.10	.19	.22	.27	-.13	-.27	.44	.33	.41	-.03	.36
Recent episode: Duration ^a	.01	.15	.04	.06	.01	-.16	.19	.09	.19	-.10	.16
Recent episode: Intensity ^a	-.00	.13	.08	.07	.04	-.18	.14	.05	.13	-.10	.08

Note. Sample 1 correlations appear above the diagonal, and Sample 2 correlations below the diagonal. In Sample 1, correlations $\geq \pm .09$ are significant at $p < .05$, those $\geq \pm .12$ are significant at $p < .01$, and those $\geq \pm .16$ are significant at $p < .001$. In Sample 2, correlations $\geq \pm .08$ are significant at $p < .05$, those $\geq \pm .10$ are significant at $p < .01$, and those $\geq \pm .12$ are significant at $p < .001$. In both studies, a positive correlation with sex indicates that women score higher than men. ^aRecent episode variables in Study 2 were analysed using Spearman's rho due to ordinal response scales.

Table 5

Direct and indirect effects of attachment on crying proneness via attitudes toward crying in Sample 1 and Sample 2

Predictor and Criterion	Mediator (Crying Attitude)	Sample 1			Sample 2		
		B	(95% CI)	R ²	B	(95% CI)	R ²
<i>Avoidance</i>							
Threat to self	Feels Better	-.01	(-.04, .01)	.55	-.01	(-.02, .00)	.54
	Healthy	-.06	(-.10, -.03)* _a		-.04	(-.06, -.02)* _a

	Healthy	.04	(.02, .07)* _a		.03	(.01, .06)* _a	
	Hatred	-.01	(-.02, .00)		-.00	(-.01, .00)	
	Control	.02	(.01, .05)* _a		.03	(.01, .05)* _a	
	Direct effect	.07	(-.02, .16)		.09	(.03, .15)*	

Note. * indicates a significant confidence interval (i.e., that does not include zero). Coefficients are estimates of the unstandardized B coefficients based on 1,000 bootstrap resamples and controlling for age and sex. Estimates within a model that do not share a subscript differ significantly in contrast analyses. Anxiety was controlled in avoidance analyses and vice versa. All models were significant overall ($ps < .001$). Standard errors vary. Coefficients in each row indicate the indirect path through that mediator, except 'direct effect' which indicates the direct effect of the attachment variable. R² refers to the total model including all predictors.

Table 6

Direct and indirect effects of attachment on most recent crying episode via attitudes toward crying (Sample 2)

Criterion	Mediator (Crying Attitude)	Avoidance		Anxiety		R^2
		B	(95% CI)	B	(95% CI)	
Recency	Feels Better	.00	(-.01, .02)	-.00	(-.28, .02)	.22
	Healthy	-.04	(-.07, -.02)* _a	.05	(.02, .09)* _a	
	Hatred	-.02	(-.05, .01)	-.00	(-.01, .01)	
	Control	-.01	(-.03, -.003)* _a	.03	(.003, .06)* _a	
	Direct effect	-.03	(-.11, .05)	.14	(.05, .22)*	
Duration	Feels Better	.01	(-.002, .03)	-.02	(-.04, .01)	.04
	Healthy	-.01	(.03, .01)	.01	(-.02, .04)	
	Hatred	.01	(-.02, .03)	.00	(-.002, .01)	
	Control	-.01	(-.03, -.001)*	.03	(.001, .06)*	
	Direct effect	.01	(-.07, .10)	.09	(.0001, .18)*	
Intensity	Feels Better	-.00	(-.01, .003)	.01	(-.01, .02)	.04
	Healthy	.00	(-.01, .01)	-.00	(-.02, .01)	
	Hatred	.02	(.005, .03)*	.00	(-.001, .01)	
	Control	-.01	(-.02, -.01)*	.02	(.01, .04)*	
	Direct effect	.00	(-.04, .04)	.03	(-.01, .07)	

Note. * indicates a significant confidence interval (i.e., that does not include zero). Coefficients are estimates of the unstandardized B coefficients based on 1,000 bootstrap resamples and controlling for age and sex. Estimates within a model that do not share a subscript differ significantly in contrast analyses. Anxiety was controlled in avoidance analyses and vice versa. All models were significant overall ($ps < .001$). Standard errors vary. Coefficients in each row indicate the indirect path through that mediator, except 'direct effect' which indicates the direct effect of the attachment variable. R^2 refers to the total model including all predictors.

Figure 1. Confirmatory factor analysis for attitudes toward crying.

Figure 2. Confirmatory factor analysis for crying proneness.

Figure 3. Proposed model.

Figure 4. Individual path coefficients for each relationship in the crying proneness mediation models.

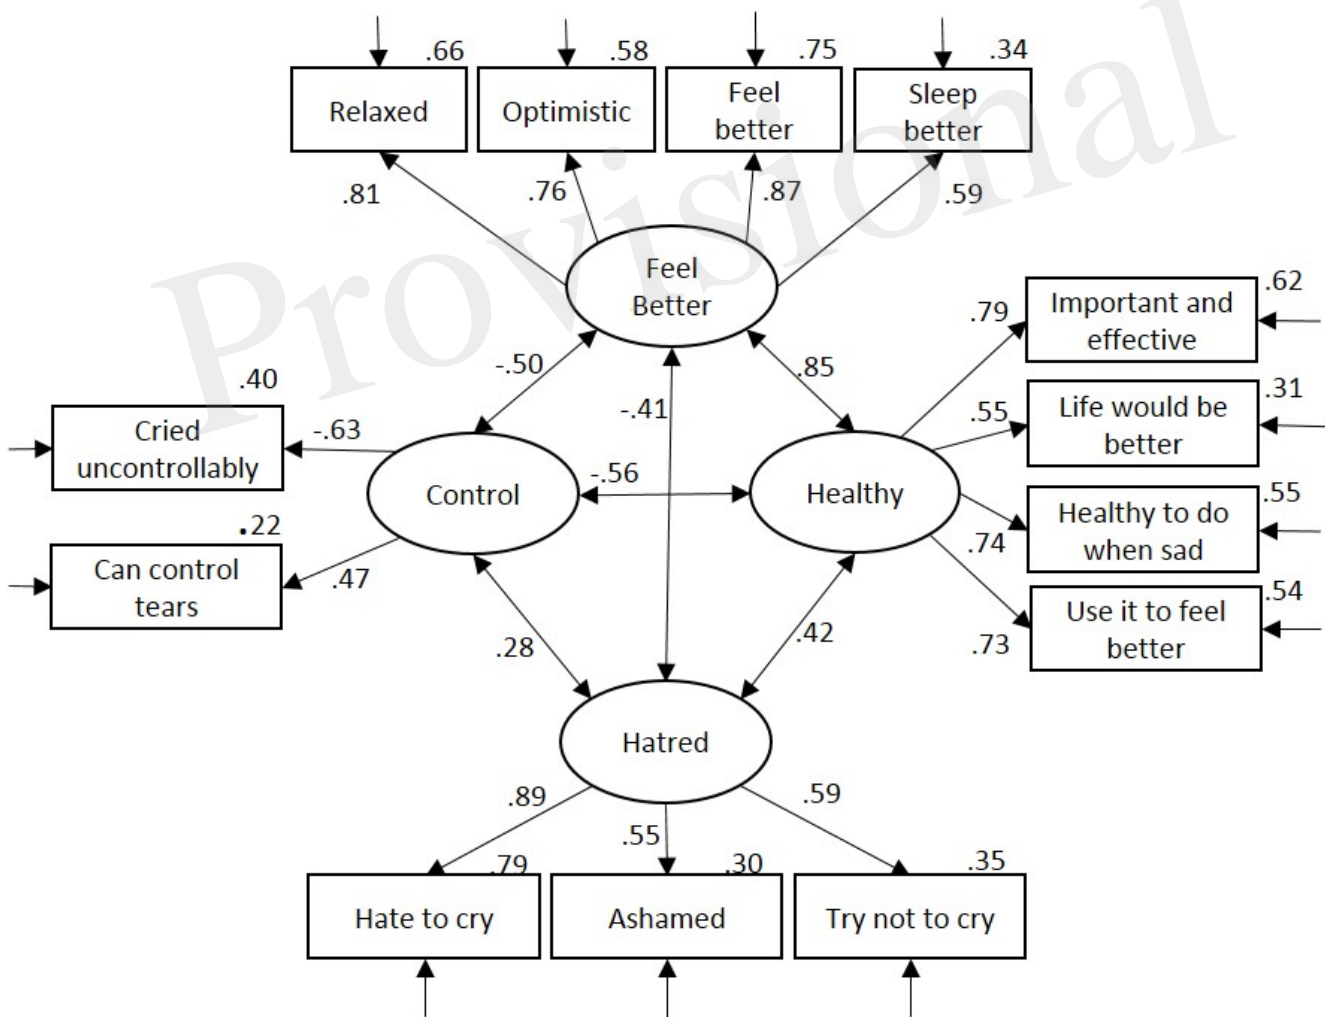

Note: S1, Sample 1, S2, Sample 2. * $p < .05$. SEs are displayed in parentheses. Paths that were non-significant in both samples are omitted for ease of interpretation. Bold lines indicate that a path was significant in both samples. Coefficients shown control for age, gender, and other coefficients, including omitted non-significant ones.

Figure 5. Individual path coefficients for each relationship in the last crying episode mediation models.

Note: SEs are displayed in parentheses. Non-significant ($p > .05$) paths are omitted for ease of interpretation. Coefficients shown control for age, gender, and other coefficients, including omitted non-significant ones.
