10 NIHR Southampton Respiratory Biomedical Research Unit, University Hospital Southampton NHS  
11 Foundation Trust, Southampton, UK

## 12 **ABSTRACT**

### 13 **Background**

14 Respiratory viruses are associated with a huge socio-economic burden and are responsible for a  
15 large proportion of acute respiratory illness in hospitalised adults. Laboratory PCR is accurate but  
16 takes at least 24 hours to generate a result to clinicians and antigen-based point-of-care tests (POCT)  
17 lack sensitivity. Rapid molecular platforms, such as the FilmArray Respiratory Panel, have equivalent  
18 diagnostic accuracy to laboratory PCR and can generate a result in 1 hour making them deployable  
19 as POCT. Molecular point-of-care testing for respiratory viruses in hospital has the potential to  
20 improve the detection rate of respiratory viruses, improve the use of influenza antivirals and reduce

1 unnecessary antibiotic use, but high quality randomised trials with clinically relevant endpoints are  
2 needed.

### 3 **Methods**

4 The ResPOC study is a pragmatic randomised controlled trial of molecular point-of-care testing for  
5 respiratory viruses in adults with acute respiratory illness presenting to a large teaching hospital in  
6 the United Kingdom. Eligible participants are adults presenting with acute respiratory illness to the  
7 emergency department or the acute medicine unit. Participants are allocated 1:1 by internet-based  
8 randomisation service to either the intervention of a nose and throat swab analysed immediately on  
9 the FilmArray Respiratory Panel as a POCT or receive routine clinical care. The primary outcome is  
10 the proportion of patients treated with antibiotics. Secondary outcomes include turnaround time,  
11 virus detection, neuraminidase inhibitor use, length of hospital stay and side room use. Analysis of  
12 the primary outcome will be by intention-to-treat and all enrolled participants will be included in  
13 safety analysis.

### 14 **Discussion**

15 Multiple novel molecular POCT platforms for infections including respiratory viruses have been  
16 developed and licensed in the last few years and many more are in development but the evidence  
17 base for clinical benefit above standard practice is minimal. This randomised controlled trial aims to  
18 close this evidence gap by generating high quality evidence for the clinical impact of molecular POCT  
19 for respiratory viruses in secondary care and to act as an exemplar for future studies of molecular  
20 POCT for infections. This study has the potential to change practice and improve patient care for  
21 patients presenting to hospital with acute respiratory illness.

### 22 **Trial Registration**

23 This study was registered with ISRCTN, number ISRCTN90211642, on 14<sup>th</sup> January 2015.

## 1 **Keywords**

2 Point-of-care test, Influenza, Respiratory virus, Adult, Hospitalised, Acute respiratory illness

## 3 **INTRODUCTION**

### 4 **Background and rationale**

#### 5 **Respiratory virus burden of disease**

6 Respiratory tract infections are the second most common cause of mortality and morbidity  
7 worldwide [1] and viruses are the most frequently detected pathogens in acute respiratory illness  
8 [2]. The influenza virus causes seasonal epidemics leading to excess hospitalisations and death  
9 mainly in the elderly and in patients with co-morbidity [3,4]. Annual seasonal influenza vaccine is  
10 recommended in at risk groups [5–7] however vaccine uptake is sub-optimal [8,9] and high quality  
11 evidence for significant protection in the elderly is lacking [10,11].

12 The rate of hospitalisation in adults with influenza has been estimated at 5 to 20 per 100,000 overall  
13 [12,13] and may be as high as 1200 per 100,000 in those over 85 years old [4]. Hospitalisation and  
14 death result from the complications of influenza including pneumonia and exacerbation of  
15 underlying cardiopulmonary conditions [14]. In adults, patients hospitalised with laboratory  
16 confirmed influenza, 10-30% are admitted to critical care units and 3-15% die in hospital [15–17]  
17 with outcomes being predicted by co-morbidity [17,18]. Estimates of the burden of influenza virus  
18 infection in hospitalised adults have traditionally been based on the incidence of the influenza-like-  
19 illness syndrome (ILI, defined as fever of  $>38^{\circ}\text{C}$  and new respiratory symptoms) rather than on  
20 laboratory confirmed influenza. ILI has poor sensitivity (around 50%) and specificity (0-63%) for the  
21 diagnosis of influenza in hospitalised adults even during periods of peak activity [19–22]. Where  
22 estimates of disease burden are based on laboratory confirmed influenza, laboratory testing of

1 patients is based on clinical suspicion of influenza and is generally targeted to patients with  
2 respiratory symptoms and fever. However, in addition to acute respiratory presentations, influenza  
3 may present as decompensated cardiovascular disease, collapse or diabetic emergencies [23,24]. For  
4 this reason many hospitalised cases of influenza are likely to remain undiagnosed. A recent Canadian  
5 study estimated that only around 1 in 14 ED visits due to influenza virus infection were correctly  
6 attributed to influenza [25]. It is likely, therefore, that the burden of influenza and other respiratory  
7 viruses amongst hospitalised adults and its economic impact have been under-estimated. In addition  
8 to influenza viruses, other respiratory viruses including rhinovirus, respiratory syncytial virus,  
9 parainfluenza viruses, human metapneumovirus and coronaviruses, cause acute exacerbations of  
10 COPD and asthma as well as other acute respiratory presentations [2], which lead to large numbers  
11 of hospitalisations every year and significant burdens upon healthcare systems.

## 12 **Conventional rapid diagnostic tests**

13 Rapid diagnostic tests for influenza based on antigen detection in nasal samples have been available  
14 for many years but have been diagnostically inaccurate in adults, where sensitivity is around 50%  
15 [26,27]. The current gold standard diagnostic test for respiratory viruses is laboratory performed  
16 polymerase chain reaction (PCR) which is highly sensitive and specific but has turnaround times of at  
17 least 24 hours and requires specialist laboratory facilities and expertise [28]. New rapid, molecular  
18 tests have recently been developed, including the FilmArray Respiratory Panel. These molecular  
19 platforms are comparable in accuracy to laboratory PCR, without the need for specialist laboratory  
20 support and expertise, and can potentially be used as a point-of-care test (POCT), but the evidence  
21 for molecular POCT improving patient outcomes is weak.

## 22 **FilmArray Respiratory Panel**

23 The FilmArray Respiratory Panel (BioFire Diagnostics, Utah, USA, owned by bioMérieux) uses nested  
24 real-time PCR to detect 20 respiratory pathogens. The FilmArray requires only 2 minutes of “hands

1 on” time and produces a test result in about one hour [29]. The FilmArray Respiratory Panel is both  
2 FDA-cleared and CE IVD marked. The viral pathogens detected by the FilmArray Respiratory Panel  
3 are: Influenza A (untyped, A/H1, A/H1-2009, A/H3), Influenza B, Adenovirus, Coronaviruses (HKU1,  
4 NL63, 229E, OC43) Human Metapneumovirus, Human Rhinovirus/Enterovirus, Parainfluenza (types  
5 1, 2, 3, 4) and Respiratory Syncytial Virus. Three bacterial respiratory pathogens are also detected:  
6 *Bordetella pertussis*, *Chlamydomphila pneumoniae* and *Mycoplasma pneumoniae* [29,30].

7 The FilmArray respiratory panel is broadly equivalent in accuracy to laboratory PCR, and use has  
8 been validated on nose and throat swabs, nasopharyngeal aspirates, lower respiratory tract samples,  
9 and samples from immunocompromised patients [30–36]. Initial mediocre sensitivity for adenovirus  
10 detection has been greatly improved [37]. All of these studies show favourable outcomes with  
11 FilmArray system, including reliability, accuracy, ease of use and turnaround time although these  
12 studies were conducted in a laboratory rather at the point-of-care and a disproportionate number of  
13 these studies were conducted from samples from children rather than adults. In terms of clinical  
14 impact, a study examining clinical outcomes in children has shown that use of the FilmArray reduced  
15 the duration of antibiotic use, the length of inpatient stay, and the time in isolation [38]. However,  
16 this was not a randomised controlled trial but examined outcomes pre- and post- implementation.  
17 To our knowledge, there have been no randomised controlled trials of this system as a point-of-care  
18 test examining the potential clinical and health economic benefits of this system. Although there are  
19 data to suggest clinical benefits (in terms of duration of hospital stay, number of investigations, and  
20 antibiotic use) for use of rapid diagnostic tests of influenza and other respiratory viruses in children  
21 [39–42] the clinical benefits and cost effectiveness of such a strategy in adults are unknown [43].

## 22 **Point-of-care testing in the wider context**

23 The Department of Health commissioned Carter report into UK pathology services noted the  
24 importance of developing clinically relevant point-of-care diagnostic tests to reduce turnaround

1 times and improve patient pathways [44]. The UK Medicines and Healthcare products Regulatory  
2 Agency (MHRA) document 'Management and Use of Point-of-Care Test Devices' sets out the context  
3 in which POCT should be considered for use and provides guidelines for their successful and safe  
4 implementation [45]. The objectives of this study are in line with these documents and it aims to  
5 examine the initial phase of a POCT programme; establishing a clinical need for the test and  
6 evaluating potential clinical benefits.

### 7 **Alignment with global research priorities**

8 In addition to being focused on patient and health care organisation outcomes, this clinical research  
9 is strongly aligned with several global research priority initiatives including the World Health  
10 Organisation's Battle against Respiratory Viruses Initiative (BRaVe) initiative [46] and the global  
11 report into antibiotic resistance [47]. The BRaVe initiative aims to catalyse multidisciplinary research  
12 on strategies to prevent and treat medically important respiratory virus infections with the goal of  
13 timely integration of research advances into public health practice. Priority areas identified include  
14 improving diagnostic tests for viral respiratory illness and improving the clinical management of  
15 patients with acute respiratory viral illness which are both addressed by this study.

### 16 **Study Aims and Objectives**

17 This study aims to prospectively evaluate whether use of a molecular point-of-care diagnostic test  
18 will improve clinical outcomes compared to routine clinical care, in adult patients presenting to the  
19 secondary care with acute respiratory illness. The primary objective of the study is to evaluate the  
20 impact of POCT on antibiotic use. The secondary objectives include evaluating the impact of POCT on  
21 influenza antiviral use, side room facility use, duration of hospitalisation and the turnaround time of  
22 results compared with standard laboratory based PCR.

### 23 **Trial design**

1 This is a pragmatic randomised controlled trial with parallel groups allocated 1:1 to the intervention  
2 (POCT) and control (routine clinical care) arms. The framework is superiority.

### 3 **METHODS**

#### 4 **Participants, interventions and outcomes**

##### 5 **Study setting**

6 This is a single centre study based in secondary care. All patients will be recruited from the Acute  
7 Medical Unit and Emergency Department of Southampton General Hospital, University Hospital  
8 Southampton NHS Foundation Trust, Southampton, UK.

##### 9 **Eligibility Criteria**

###### 10 Inclusion Criteria

- 11 • Aged 18 years or over
- 12 • Has the capacity to give informed, written consent and is able and willing to adhere  
13 to the study procedures
- 14 • Is a patient in Southampton General Hospital's AMU or ED
- 15 • Can be recruited to the study
- 16 - within a 24 hour period of first triage by ED staff OR
- 17 - within a 24 hour period of arrival on AMU (if admitted directly to AMU)
- 18 • Has an acute respiratory illness\* and / or fever >37.5°C

- 1           •       Duration of illness less than or equal to 7 days

2   \*An episode of acute respiratory illness is defined as an acute pulmonary illness (including  
3   pneumonia, bronchitis and influenza-like illness) or an acute exacerbation of a chronic respiratory  
4   illness (including exacerbation of COPD, asthma or bronchiectasis).

5   Provisional or suspected clinical diagnoses of acute respiratory illnesses are made by an AMU or ED  
6   clinician.

7   Exclusion Criteria

- 8           •       Patients not fulfilling inclusion criteria

- 9           •       A palliative approach being taken by the treating clinicians

- 10          •       Previously included in this study and re-presenting within the last 30 days after  
11          hospital discharge

- 12          •       Declines nasal / pharyngeal swabbing

13   Concurrent, prior or subsequent enrolment in an observational study is not necessarily an exclusion  
14   criterion; this is at the discretion of the chief investigator.

15   **Interventions**

16   For those randomised to the interventional arm

17   A nose and throat swab will be taken by a member of research staff (doctor or nurse) according to  
18   standard protocols. Swabs are placed directly into viral transport medium. The sample is analysed on  
19   the FilmArray Respiratory Panel as per training delivered by the apparatus manufacturer. Test  
20   results are normally available in about an hour using the FilmArray Respiratory Panel. In the event of

1 a run failure, the analysis run will be repeated using the same sample. The FilmArray machines are  
2 located in or near the patient-care areas. The results of the test will be documented in the patient's  
3 case notes and in the event of a pathogen being detected, a doctor from the clinical team  
4 responsible for the patient will be directly informed. The participant will also be informed of the  
5 result on the same day.

#### 6 For those randomised to the control group

7 These patients will be managed using routine clinical care, as per current practice in this large  
8 teaching hospital in the United Kingdom, which is a justifiable comparator. Respiratory virus testing  
9 using laboratory PCR will be at the discretion of the responsible clinical team.

#### 10 For both groups

11 A subgroup of participants may be approached for venous blood sampling and additional  
12 nasal/throat swabs to be stored for further study including immunological testing and viral  
13 sequencing. All samples will be stored devoid of participant identifiable information to protect  
14 participant confidentiality.

### 15 **Outcomes**

#### 16 Primary outcome

- 17 • Proportion of patients treated with antibiotics, measured retrospectively from case  
18 notes for the entire duration of hospitalisation or at 30 days, whichever is shortest

#### 19 Secondary outcomes

- 20 • Median duration of antibiotic use, days
- 21 • Proportion of patients receiving only a stat dose of antibiotics

- 1 • Proportion of patients receiving <48 hours antibiotics
- 2 • Proportion of patients receiving intravenous antibiotics
- 3 • Median duration of intravenous antibiotics, days
- 4 • Proportion of patients with influenza treated with influenza antivirals
- 5 • Proportion of influenza antiviral use occurring in patients with influenza
- 6 • Median time to influenza antiviral use, hours
- 7 • Median duration of influenza antivirals, days
- 8 • Median duration of hospital stay, days
- 9 • Proportion of patients admitted to a side room
- 10 • Median duration of side room use, days
- 11 • Median time to isolation or de-isolation, days
- 12 • Median length of hospital stay, days
- 13 • Median turnaround time of respiratory viruses testing, hours
- 14 • Proportion of patients with viruses detected
- 15 • Proportionate mortality in hospital and at 30 days post randomisation
- 16 • Proportion admitted to Intensive care or high dependency units
- 17 • Proportion re-presenting to hospital within 30 days
- 18 • Proportion re-admitted to hospital within 30 days
- 19 • Proportion with prolonged in-patient stay

## 20 **Participant timeline**

21 Patients are identified in the AMU and ED by research staff according to eligibility criteria and once  
22 written informed consent is obtained they are immediately randomised to the intervention or  
23 control group. Those randomised to the intervention groups have a nose and throat swab performed  
24 immediately by the research team and this is then tested on the Film array machine. Results are

1 available after approximately 1 hour and are immediately communicated to the clinical team.  
2 Clinical data is then collected retrospectively for both groups. There are no follow up visits for either  
3 group.

#### 4 **Sample size**

5 Sample size is based upon the primary outcome measure of proportion of patients treated with  
6 antibiotics. Previous studies have demonstrated that around 75% of patients hospitalised in the UK  
7 with acute respiratory illness are treated with antibiotics [2]. Two small studies in hospitalised adult  
8 patients with acute respiratory illness have demonstrated reductions in the proportion of patients  
9 treated with antibiotics of around 10-15% in those tested for respiratory viruses [43,48]. To detect a  
10 reduction in antibiotic use from 75% to 65% with a power of 0.8 and significance level of 0.05, 326  
11 patients would be required in each group. Allowing for withdrawals in up to 10% of patients we aim  
12 to recruit 360 patients to each group (720 patients in total).

#### 13 **Recruitment and Screening**

14 Eligible patients in the emergency department (ED) and acute medicine unit (AMU) of Southampton  
15 General Hospital will be identified by research staff who will regularly review the comprehensive IT  
16 admissions systems in each area on a daily basis. Recruitment will run from January 2015 until April  
17 2015 and from October 2015 to April 2016 in order to include the periods of peak influenza  
18 circulation for those seasons.

#### 19 **Assignment of interventions**

#### 20 **Sequence generation, allocation concealment and implementation**

21 Once an eligible patient has been screened, and given fully informed, written consent they will be  
22 enrolled and assigned a unique participant identification number consecutively. A study team

1 member will then use a dedicated internet-based randomisation service (sealedenvelope.com,  
2 which uses random permuted blocks of varying sizes) to obtain a computer generated randomisation  
3 code for the patient which will assign them to either the intervention or control group. Research  
4 staff will implement the allocation sequence and assign the patients to the group based on the  
5 allocation code from sealedenvelope.com.

## 6 **Blinding**

7 As this is a pragmatic trial of a diagnostic device no attempt at blinding trial participants, research  
8 staff or care providers will be made. Data analysts will be blinded to group allocation.

## 9 **Data collection, management and analysis**

### 10 **Data collection methods**

11 Clinical and demographic data will be collected at the time of enrolment by research staff from  
12 patient paper case notes and electronic medical records. Outcome data will be collected  
13 retrospectively by research staff from paper case notes, electronic medical records, electronic  
14 prescribing systems, and electronic radiological and laboratory results systems. Final clinical  
15 diagnosis will be based on clinical discharge coding and discharge summaries. All source data will be  
16 entered into a standardised paper case report form. Patients withdrawn from the study will have no  
17 further data collected.

### 18 **Data management**

19 The study will be conducted in accordance with the approved protocol, ICH GCP relevant regulations  
20 and standard operating procedures. Data will be evaluated for compliance with the protocol and  
21 accuracy in relation to source documents. Data from case report forms will be entered into a secure  
22 bespoke database at the completion of the study followed by data lock. All data will be anonymised:

1 volunteer participant data will be identified by a unique study number in the CRF and database. A  
2 separate confidential file containing identifiable information will be stored in a secured location in  
3 accordance with the Data Protection Act 1998. Only the Sponsor's representative and investigators  
4 will have access to the information.

## 5 **Statistical methods**

6 This will be performed by a dedicated medical statistician from the University of Southampton  
7 independent from the study team. Patients tested with the rapid diagnostic test will be compared  
8 with patients treated by routine clinical care using standard descriptive and comparative statistical  
9 methods using Prism (GraphPad Software Inc; La Jolla, California) and SPSS (SPSS, Inc; Chicago,  
10 Illinois). Summaries of all baseline characteristics will be presented using means and standard  
11 deviations, medians and interquartile ranges, or frequencies and percentages, as appropriate.  
12 Analysis of the primary outcome will be by intention-to-treat and will compare the proportion of  
13 patients receiving antibiotics using the chi-square test for equality of proportions between groups.  
14 The effect of group (intervention or control) on the primary outcome will be further assessed using  
15 logistic regression to control for demographics (age, sex) and other co-variables. For secondary  
16 outcomes the intervention and control groups will be compared using chi-square tests for equality of  
17 proportions for binary data (including proportions) and using t-tests and non-parametric equivalent  
18 tests for continuous data (e.g. turnaround time) as appropriate.

## 19 **Monitoring**

### 20 **Data monitoring**

21 The study was reviewed by the sponsor and felt to be of low risk on the grounds of the non-CTIMP  
22 nature and the low likelihood of harms associated with the intervention. Therefore the creation of a  
23 data monitoring committee was not felt necessary. No interim analysis of data is planned.

## 1 **Harms**

2 The risks of nose and throat swabs and additional blood tests being taken are minimal and where  
3 occurring are likely to be mild. No additional adverse events s related to POCT for respiratory viruses  
4 are anticipated. However active monitoring and reporting of severe adverse events will be  
5 undertaken. Serious adverse events (SAE) are defined here as:

- 6 • Death during admission or within 30 days of enrolment
- 7 • Admission to the intensive care unit
- 8 • Evidence of prolonged hospital stay
- 9 • New or persistent significant disability or incapacity
- 10 • Evidence of congenital anomaly or birth defect

11 As participants in ED are not yet hospitalised but have a reasonable likelihood of being admitted to  
12 hospital, patients enrolled in ED who are subsequently admitted to the hospital will not  
13 automatically be counted as having experienced a SAE. Participants who are already admitted to  
14 AMU are already hospitalised however, an adverse event leading to prolongation of their existing  
15 hospitalisation will be counted as an SAE.

## 16 **Auditing**

17 Regular monitoring will be performed according to ICH GCP by the sponsor. Data will be evaluated  
18 for compliance with the protocol and accuracy in relation to source documents. Following written  
19 standard operating procedures, the monitors will verify that the clinical trial is conducted and data  
20 are generated, documented and reported in compliance with the protocol, GCP and the applicable  
21 regulatory requirements.

## 22 **Protocol amendments**

1 All protocol modifications were communicated to investigators and to trial registries. Two  
2 amendments to the protocol have been approved by the ethics committee, the first, to change the  
3 study from a pilot study into a full study and to amend an exclusion criterion, the second, to add a  
4 laboratory analysis plan for the samples collected (current protocol version 3.0, date 26<sup>th</sup> January  
5 2016). The local study reference is RHM MED1217.

## 6 **Confidentiality**

7 All data will be anonymised to protect participant confidentiality: volunteer participant data will be  
8 identified by a unique study number in the case report forms and database. Serious Adverse Events  
9 will be reported in line with Good Clinical Practice and regulatory requirements. All study staff are  
10 trained in Good Clinical Practice. Only the investigators and sponsor's representative (monitor) have  
11 access to the data, which is kept securely.

## 12 **Access to data**

13 The final data set will be wholly accessible to the principal investigator, co-investigators and  
14 independent statistician and may be made available to other parties on request.

## 15 **Dissemination policy**

16 Authorship of this and subsequent manuscripts stemming from this protocol will follow the ICMJE  
17 recommendations, and CONSORT statement where appropriate, and there is no intent to use  
18 professional writers. There are no plans to make the dataset publically available. Beyond the study  
19 team and regulatory oversight, the full protocol is only made available at the discretion of the chief  
20 investigator. The data and samples collected are expected to form multiple publications, and these  
21 publications must acknowledge this trial and study team as appropriate.

## 22 **DISCUSSION**

1 This study has the potential to improve patient care by changing practice and contribute to a health  
2 economic analysis. The outcome measures are clinically important to a large number of patients, and  
3 also crucial in antimicrobial stewardship and healthcare resource management. As a randomised  
4 controlled trial, this study will provide high-quality evidence for the potential use of molecular point-  
5 of-care testing for respiratory viruses in hospitalised adults. Beyond this trial, molecular point-of-  
6 care testing for common pathogens in select populations, such as in intensive care, or other  
7 common illness presentations, such as gastroenteritis, needs to be evaluated to further improve  
8 patient care and effectively manage healthcare resources.

- 18 SAE, Serious adverse event

1 **DECLARATIONS**

2 **Ethics approval and consent to participate**

3 Approval was obtained prior to study start from National Research Ethics Service Regional Ethics  
4 Committee North West - Preston (reference NW /14/1467). Two amendments to the protocol have  
5 been approved by the ethics committee, the first, to change the study from a pilot study into a full  
6 study and to amend an exclusion criterion, the second, to add a laboratory analysis plan for the  
7 samples collected (current protocol version 3.0, date 26th January 2016). The local study reference is  
8 RHM MED1217. Written, informed consent is obtained from each patient-participant by research  
9 staff (by research nurse, research fellow or the principal investigator) prior enrolment and  
10 randomisation. Consent was obtained to obtain and store specimens (blood and nose/throat swabs)  
11 for additional research studies from some patients.

12 **Consent for publication**

13 Not applicable

14 **Availability of data and material**

15 Not applicable

16 **Competing interests**

17 The principal investigator and co-investigators declare that they have no competing interests  
18 relating to this study.

19 **Funding and support**

20 1. University of Southampton, Faculty of Medicine, Research Management Committee Pump Priming  
21 Grant.

1 2. University Hospital Southampton NHS Foundation Trust and NIHR Respiratory Biomedical  
2 Research Unit provided research nurses, clinical trials assistants and data managers to support this  
3 trial.

4 3. NIHR Southampton Wellcome Trust Clinical Research Facility, University Hospital Southampton  
5 NHS Foundation Trust provided clinical fellows to support this trial.

6 4. NIHR Clinical Research Network, Wessex provided clinical fellows to support this trial.

7 The study sponsor, study funders and manufacturers of the FilmArray platform had no involvement  
8 in the conception, design or running of this study and will have no involvement in the analysis of the  
9 data or writing of subsequent manuscripts for publication. Equipment and consumable are  
10 purchased from bioMérieux, UK.

## 11 **Authors' contributions**

12 TWC conceived the study and is the chief and principal investigator. TWC and NJB designed the  
13 study. NJB, AKM and TWC wrote the protocol.

## 14 **Acknowledgements**

15 We thank the patients and staff in the Emergency Department and Acute Medicine Unit at University  
16 Hospital Southampton NHS Foundation Trust in making this study possible.
