Analysis of through-thickness thermal conductivity of wind turbine blade CFRP materials

University of Southampton, Southampton, UK

Introduction

Unidirectional CFRP laminates with a fibre volume content of 57% were manufactured using Vacuum Assisted Liquid Resin Infusion in three different thicknesses to assess the measuring capabilities of the apparatus. The through-thickness thermal conductivity was examined by means of a steady-state technique based on the Guarded Hot Plate (GHP) method. By establishing one-dimensional heat flow through the sample and measuring the heat flux the thermal conductivity was determined.

To validate the technique, measurements were conducted in two different materials with well-defined values. PTFE and Fused Silica samples were employed as reference materials. Calibration runs showed good correlation with the expected literature values for both of the reference materials. Consistent results were obtained for all three laminate thicknesses thus validating the efficiency and accuracy of the technique.

Description of apparatus

- Steady-state technique based on the guarded hot plate method
- Direct heat flux readings from a thin film flux sensor, Omega HFS-4
- A screw actuator was utilised to apply 0.28 MPa to improve interface conductance and to promote reproducibility
- Steady-state conditions were achieved with temperature fluctuations were not higher than ±0.5°C for more than 30 min
- Assuming one-dimensional heat flow the thermal conductivity were calculated with the use of eq.1
- A silicone based thermal paste, Electrolube HTSP, was utilised to mitigate the interfacial thermal resistance

\[ q = -k \frac{\Delta T}{\Delta x} \]  

Where, 
- \( q \) (W/m²) is the heat flux, 
- \( k \) (W/mK) is the thermal conductivity and 
- \( \frac{\Delta T}{\Delta x} \) is the temperature gradient over the sample’s thickness.

Results

- The mean heat flux during the measurements was 1380 W/m²
- Each sample was tested at least twice
- Estimations of interface conductance were realised by plotting \( \Delta T/\Delta x \) versus \( q \) for three different sample thicknesses
- Interface conductance was found to be 1100 W/m²K
- Corrections on the measured values were made with the use of eq.2

\[ \frac{1}{k} + \frac{\Delta x}{k_{\text{true}}} = \frac{\Delta x}{k_{\text{meas}}} \]  

Where, 
- \( h \) (W/m²K) is the interface conductance
- \( \Delta x \) (m) is the sample’s thickness
- \( k_{\text{true}} \) (W/mK) is the corrected thermal conductivity value
- \( k_{\text{meas}} \) (W/mK) is the measured thermal conductivity value

Conclusion

- The technique is simple and applicable in a wide range of sample thicknesses
- Measurements can be achieved in a wide range of polymers and polymer matrix composites
- No additional information about the sample are required besides its thickness
- The higher discrepancies observed in the 2-ply laminate are associated with the sample’s aspect ratio
- Minor alterations in the sample design will enable the characterization of the transverse direction thermal conductivity
