- 37
- 38 Essential Thrombocythemia (ET) is a myeloproliferative neoplasm (MPN) defined by
- 39 thrombocytosis, increased risk of vascular thrombosis,^{1,2} hemorrhage³ and progression to
- 40 myelofibrosis (MF)^{4,5} and acute myeloid leukemia (AML).^{4,5} Patients are risk-stratified to
- 41 identify those who might benefit from cytoreduction to reduce the risk of vascular
- 42 complications.⁶ Resistance/intolerance to hydroxycarbamide (HC-RES/INT), a first-line
- 43 cytoreductive treatment, develops in 20% of high-risk patients⁷ with increased risk of
- 44 disease progression and reduced survival.⁸ New approaches are needed to predict disease
- 45 transformation risk in these patients, together with development of therapies that reduce this
- 46 risk.
- 47

48 Following the discovery of the Janus Kinase 2 (JAK2) mutation (JAK2V617F), present in 49 ~50% of ET,⁹ the first approved JAK1/JAK2 inhibitor, Ruxolitinib (RUX), is now widely used for treatment of myelofibrosis¹⁰ and polycythemia vera.¹¹ The MAJIC trial explored the role of 50 51 RUX in HC-RES/INT ET, randomizing patients 1:1 to RUX or best available therapy (BAT), 52 demonstrating similar rates of 1-year complete hematological response (CHR).¹² Mutational 53 status was not comprehensively reported in this paper. This is important as ET patients (29-54 72%)^{13,14} carry mutations in non-MPN driver genes (NDM). Inferior prognosis is associated 55 with specific mutations at diagnosis.¹⁴ The impact of NDM in HC-RES/INT ET is unknown, as 56 is the effect of RUX on disease course in molecularly defined subgroups. We therefore 57 evaluated mutational status of MAJIC-ET patients and correlated this with clinical outcomes. 58 59 Next generation sequencing (NGS) was performed at baseline (n=110) and serially if a later 60 sample was available (see Supplemental Methods for NGS and statistical analysis 61 methodology). Median follow-up was 55 months (95% confidence interval [CI], 49.9-60.4). 62 JAK2, CALR and MPL mutations were present in 49.1%, 30% & 4.5% of patients, 63 respectively and 16.4% of patients were "triple-negative" (TN). Baseline NDM were present 64 in 30% (n=33) of patients with >1 present in 10% (Figure 1A), most frequently TET2 (n=12), 65 TP53 (n=7) and SF3B1 (n=7) genes (Figure 1B; Supplemental Table 1). Driver mutation 66 variant allele frequency (VAF) was higher than NDM VAF in 66.67%, 87.5% and 20% of 67 JAK2, CALR and MPL-mutated patients respectively (Figure 1C).¹⁵ Patients with NDM 68 tended to be older with lower hemoglobin levels (Figure 1D, Supplemental Table 2). TP53 69 mutations trended towards a higher frequency in TN (17.6%) than in JAK2/CALR/MPL-70 mutated patients (4.3%), p=0.073. In the primary analysis, driver mutation status did not 71 correlate with CHR¹². Since platelet count reduction is a key therapeutic goal, we performed 72 a post-hoc analysis defining platelet response as <400 x 10⁹/l at 1-year. RUX-treated 73 JAK2V617F-mutated patients had significantly more platelet responses than JAK2V617F 74 wild-type (WT) patients, a difference not seen for BAT-treated patients (Figure 1E). RUX 75 discontinuation was most often due to treatment failure and this correlated with non 76 JAK2V617F-mutated status (OR 6.1 [95% CI 1.43–26.6], p=0.015). NDMs did not influence 77 hematological/symptom responses (Supplemental Table 3). 78

79 Transformation events occurred in 12.7% (Supplemental Table 3). *TP53*-mutated patients

80 had inferior 4-year transformation-free survival (TFS) of 42.9% (95% CI 9.8–73.4%) versus

81 79.8% (95% CI 69.7–86.8%) for WT patients, p=0.011 (Figure 2A). Splicing factor (SF)

82 mutations conferred a poorer 4-year TFS of 40% (95% CI 12.3–67%) versus 81.5% for WT

patients (95% CI 71.4–88.3%; p=0.00039, Figure 2B); predominantly attributable to mutated-

84 SF3B1 (p=0.004). High molecular risk (HMR) mutations in this cohort (defined by SF and

- 85 TP53 mutations) conferred a poorer TFS (p<0.0001, Figure 2C) which was not ameliorated 86 by RUX (Figure 2D). HMR mutations retained their negative impact on multivariable analysis
- 87 (Figure 2E). Driver mutation VAF ≥50% and male gender independently conferred a poorer
- 88 TFS, findings reported by other groups.^{16,17} Mutated-*TET2* did not correlate with clinical
- 89 outcomes, comparable to previous findings.¹⁴
- 90

91 Thrombotic (19.1%, n=21/110) were not influenced by mutational status overall. This is in

- 92 contrast to previous studies reporting a greater thrombotic risk in JAK2V617F-mutated
- 93 patients.⁴ Whilst a possible explanation is that this association is not seen in HC-RES/INT
- 94 patients, the number of events in our study is small and should therefore be interpreted with
- 95 caution. Hemorrhagic events (9.1%, n=10/110) were specifically associated with SF
- 96 mutations, p=0.007 (Supplemental Table 3). Grade 3/4 hematological toxicities were not
- 97 associated with mutational status. Overall survival at 4-years of 91.5% (95% CI 80.2-96.4%)
- 98 in BAT and 83% (95% CI 70.4-90.5%) in RUX arms (p=0.22) was not influenced by
- 99 mutational status.
- 100
- 101 1-year driver mutation molecular responses (MR) were rare (n=3), occurring exclusively in
- 102 the RUX arm; a complete MR (CMR) in 2 patients (JAK2V617F-mutated and CALR-
- 103 mutated) and one CALR-mutated partial MR (PMR). Longitudinal driver mutation analysis
- 104 was performed in 54% (n=50/93); median analysis time 48 (24-60) months with no
- 105 significant change in VAF at any time point (Supplemental Figure 1A & B). 1-year MR was
- 106 lost in 2 patients (Supplemental Figure 1C & D). Longitudinal NDM analysis was possible in
- 107 52% (n=57/110); median analysis time 40 (6-60) months. New NDM, defined by
- identification at VAF \geq 5%, were detection in 19.3% (n=11/57) at a similar frequency across 108
- 109 treatment arms (Supplemental Table 4) and no significant correlations were detected with
- 110 baseline NDM or clinical/survival outcomes. However, a median follow-up time of 10.7
- 111 months (95% CI 9.05–12.4) after later NDM analysis is not sufficient time for survival
- 112 analysis. These data highlight the clinical utility of serial molecular analysis in HC-RES/INT ET.
- 113
- 114

115 In this analysis, we identify NDM at baseline in 30% of patients, a higher frequency than most previous analyses, which may relate to this high-risk nature of this cohort.^{13,14,16,18} TP53 116 117 and SF3B1 mutations were observed each at 6.4%, higher than previously reported in ET (~2 and 2-5% respectively).^{13,14,16,19} The frequent detection of *TP53* mutations in TN patients 118 was unexpected but the numbers are too few (n=3) to draw firm conclusions. Disease 119 transformation was specifically associated with SF (most commonly SF3B1) and TP53 120

121 mutations, determining a HMR for this cohort. However, this requires independent validation

- in larger cohorts before being applied in clinical practice. *TP53* mutations in MPNs have
- been associated with AML transformation^{14,16} but have not been reported to increase
- 124 myelofibrotic transformation in ET.^{14,16} Myelofibrotic transformation has been reported in
- association with SF mutations in ET, most often mutated-*SF3B1*,^{14,20} but a recent large MPN
- 126 study, identified *SRSF2*, *ZRSR2* and *U2AF1* but not *SF3B1*¹⁶ as myelofibrotic transformation
- 127 predictors in ET. This contrasts with myelodysplastic syndromes where *SF3B1* mutations
- 128 confer better survival²¹⁻²³ with lower risk of disease progression²¹ suggesting disease context
- and co-mutations (primarily *JAK*2V617F here) are relevant.
- 130
- 131 Importantly, disease transformation in patients with HMR-NDM was not mitigated by RUX
- 132 which is noteworthy as there has been interest in the possibility that early intervention with
- 133 JAK2 inhibition might attenuate disease progression. We observed a novel association
- 134 between SF mutations and hemorrhagic events; this finding needs independent
- 135 corroboration due to low event rate. We also found that *JAK*2V617F-mutated status
- 136 correlated with improved platelet responses to RUX, and notably, more non-JAK2V617F
- 137 mutated patients stopped RUX raising the possibility that *JAK*2V617F-mutated ET patients
- 138 might selectively benefit from RUX.
- 139
- 140 In summary, we report for the first time, comprehensive mutational analysis of HC-RES/INT
- 141 ET within the context of a prospective randomized clinical trial. We found a particularly high
- 142 prevalence of *TP53* and splicing factor mutations, which was strongly predictive of
- subsequent disease transformation, and was not mitigated by RUX. This highlights the
- 144 clinical/prognostic utility of serial mutation screening in HC RES/INT ET to allow
- identification of patients at risk of disease transformation.

292

293 Figure 2. Kaplan-Meier curves of transformation-free survival (TFS) stratified by mutational statuses with survival estimates, reported at 4-years. (A) TP53 mutations 294 295 were associated with inferior 4-year TFS; TP53-mutated (42.9% [95% CI 9.8 - 73.4%]) vs. TP53-wild type (WT) patients (79.8% [95% CI 69.7 - 86.8%]), p=0.011. (B) SF mutations 296 297 conferred a poorer 4-year TFS; SF-mutated (40% [95% CI 12.3 - 67%]) vs. SF-WT (81.5% 298 [95% CI 71.4 – 88.3%]), p=0.00039. (C) Comparing patients with HMR with LMR at 4-years; 299 HMR 41.2% (95% CI 23.3-72.7%) vs. LMR 84.6% (95% CI 76.9 – 93.1%), p<0.0001. (D) 300 Stratifying patients with high risk molecular (HMR) mutations in this study by treatment arm demonstrates no amelioration of negative impact of HMR mutation with RUX treatment; 301 302 patients with HMR on RUX had TFS at 4-years of 36.4% (95% CI 26.2 - 46.6%) and on BAT 303 50% (29.1 – 67.7%) (p=0.505 between these arms) as compared to those without these 304 mutations (i.e. low molecular risk, LMR) with TFS at 4-years of 84.7% (95% CI 71.6 – 92%) 305 on RUX and of 90.6% (95% CI 78.5 – 96%) on BAT (p=0.101 between these arms). The log-306 rank test was used to compare survival estimates between groups. (E) Forest plot showing 307 multivariable cox model of transformation-free survival (TFS). Covariates significant on 308 univariate analysis were included; TP53 mutations, SF mutations, treatment arm, JAK2V617F mutation status, disease duration at trial entry (TE), age and gender. HMR 309 310 mutations independently retained negative impact on TFS with a hazard ratio (HR) of 4.21, 311 p=0.006. Treatment arm, JAK2V617F status, disease duration at TE and age were not 312 significant but notably male gender was associated with a poorer TFS, HR 4.5, p=0.006. Driver mutation allele ≥50% was independently associated with a poorer TFS, HR 4.11, 313 314 p=0.016. Age and disease duration at TE were categorized as continuous variables. 315 CI=confidence interval; HR=hazard ratio; HMR=high molecular risk risk (SF and TP53 316 mutations); LMR=low molecular risk (without SF or TP53 mutations); JAK2=JAK2V617F; 317 NDM=non-MPN (myeloproliferative neoplasm) driver mutation; SF=splicing factor mutation 318 (SF3B1, ZRSR2, SRSF2); WT=wild type. 319

Supplemental Table 1. List of baseline NDM including genomic position, nucleotide change, protein consequence, mutation type and variant allele frequency (VAF).

Supplemental Table 2. Baseline clinical characteristics in patients with and without non-MPN driver mutations (NDM).

Differences were analyzed using the chi-squared test for categorical variables or fisher's exact test if a value less than 5 in any cells of the contingency table and non-parametric Mann-Whitney U test for continuous variables (i.e. age, disease duration, blood counts). MPN=myeloproliferative; patients=patients; n=number; BAT=best available therapy; Hb=hemoglobin; HC=hydroxycarbamide; Hct=hematocrit; NPM=non-MPN (myeloproliferative neoplasm) driver mutation; P32=radioactive phosphorus; Plt: platelet count; RUX=ruxolitinib; y=years; TN=triple negative; WBC=white blood cell count.

Baseline Clinical Characteristics		Patients with NDM n (%)	Patients without NDM n (%)	Ρ
All patients (n=110)		33 (30)	77 (70)	
Median age i	n years (range)	71 (44 – 91)	64 (35 – 85)	0.0001

CALR allele burden ≥50%		0/7 (0)	2/26 (7.7)	1.0

Supplemental Table 3. Logistic regression predicting the influence of non-MPN

driver mutations (NDM) on clinical outcomes. All models were adjusted for *JAK2*V617F mutation status and treatment type since patients were stratified by these at trial entry. Further adjusted analysis was performed for outcomes with significant (p<0.05) odd ratios (OR) on initial analysis to include age, TE hemoglobin level and platelet counts denoted indicated with "(adj)" next to OR. The presence of a HMR mutation significantly increased the odds of a transformation event, p=0.015. Hemorrhagic events outcomes were associated specifically with the presence of SF mutations. Platelet counts closest to the hemorrhagic event were normal in 3 of these SF-mutated patients and reduced (*ZRSR2*- mutated; $54 \times 10^9/I$) and elevated (*SF3B1*-mutated, $504 \times 10^9/I$) in one patient each. adj=adjusted; AML=acute myeloid leukemia; CHR=complete hematological response; CI=confidence interval; ELN; European LeukemiaNet; HMR=high molecular risk mutation (SF and/or *TP53* mutations); MF=myelofibrosis; n_E =number of events; non-MPN (myeloproliferative neoplasm) driver mutation; OR=odds ratio; RUX=ruxolitinib; SF= splicing factor mutation (*SF3B1, ZRSR2, SRSF2*); TE=trial entry; UV=univariate. *Driver mutation allele burden ³50% and gender also included in final model for transformation.

Outcome (n _E)	OR (UV)	OR 95% CI	Р
1-year CR (ELN) (n _E =50)	0.72	0.3 – 1.6	0.43
1-year post hoc platelet response (n _E =55)	0.5	0.2 - 1.2	0.12
1-year Overall symptom score response (³ 50% reduction) (n _E =12)	0.71	0.2 - 2.6	0.61
Transformations (MF n _E =13, AML n _E =1)	3.8 (NDM) (adj)* 14.4 (HMR) (adj)*	0.7– 21.5 1.7-122.8	0.129 0.015
Thrombotic event (n _E =21)	0.75	0.2 – 2.3	0.62
Hemorrhagic event (n _E =10)	2.1 (NDM)(adj) 18.9 (SF)(adj)	0.5 – 10 2.2 - 161	0.34 0.007
Death (n _E =13)	2.14	0.6– 2.3	0.21
Stopping RUX treatment (n _E =40)	0.38 (adj)	0.7 – 1.9	0.25

Supplemental Table 4. List of new follow-up NDM including genomic position, nucleotide change, protein consequence, mutation type and variant allele frequency (VAF).

ID	Gene	Genomic position	Nucleotide change	Protein consequence	Mutation type	VAF (%)

Supplemental Figure 1. (A) Waterfall plot of driver mutation change in VAF for each patient at 12months; median change 15.3% (0-400%) and (B) driver mutation change in VAF from 12m to latest time point; median 21.6% (0-389%). (C) BAT-treated patient achieving a JAK2 V617F CMR at 12 months; VAF 22 to 0%. Subsequently, they had a loss of CMR at 44 months with JAK2 V617F VAF 4% coinciding emergence of low level TET2 mutation. (D) RUX-treated patient achieving a CALR PMR at 12 months; VAF 65 to 9%. Subsequently, they had a loss of PMR with a CALR VAF 44% at 60 months and antecedent to this, an ASXL1 mutation emerged at 56 months. Notably, this patient switched from RUX at 20 months due to toxicity. BAT=best available therapy; CMR=complete molecular response; VAF=variant allele frequency; RUX=ruxolitinib; PMR=partial molecular response; TE=trial entry; n=number.

1 Supplemental Methods

2

3 Inclusion criteria and outcome measures were previously reported.^{1,2} Peripheral blood (PB) 4 and bone marrow (BM) samples were collected from all patients at baseline and serially, PB 5 samples every 3-4 months and BM samples annually during the study period. Genomic DNA 6 (qDNA) was isolated using DNeasy Blood and Tissue Kit (Qiagen) as per manufacturer's 7 instructions from either PB whole blood or stored PB granulocyte pellets. Driver mutations 8 were sequenced using a next generation sequencing assay as previously described.³ 9 Mutational profiles of NDM were analyzed using an International Organization for Standardization Standardization (ISO 15189:2012) accredited Illumina TruSeg Custom 10 11 Amplicon Panel including 32 gene mutation hotspots & exons frequently mutated in myeloid malignancies (~56,000 bp, 341 amplicons); ASXL1, ATRX, DNMT3A, EZH2, TET2, CEBPA, 12 13 ETV6, NPM1, PHF6, RUNX1, SETBP1, SF3B1, SRSF2, TP53, U2AF1, WT1, ZRSR2, CBL, 14 CBLB, CBLC, CSF3R, FLT3, HRAS, JAK2, KIT, KRAS, MPL, NRAS, PDGFRA, PTEN, 15 *IDH1, IDH2.*⁴ Paired-end indexed libraries were prepared for each patient and sequenced on 16 the Illumina MiSeq platform. FASTQ files were aligned to the reference genome 17 (GRCh37/hg19). The minimum depth was ≥100 reads per base and minimum accepted 18 coverage was achievement of this depth in ≥95% of targeted bases. Acceptable coverage 19 was achieved in 99.1% (109/110) of patients. Alignment and variant calling were performed 20 in Basespace (utilizing BWA and GATK/Somatic variant caller; Illumina), while filtering and 21 annotation were performed using a combination of Variant Studio (Illumina) and a custom 22 designed in-house algorithm to evaluate the variants identified. Pathogenic significance of each variant was determined using Exome Aggregation Consortium (ExAC) population 23 24 frequencies, the Single Nucleotide Polymorphism database (dbSNP), the Catalogue Of 25 Somatic Mutations In Cancer (COSMIC) databases and published literature. Variants 26 considered pathogenic included those reported as somatic in COSMIC and not found in 27 germline databases, those present at the same genomic location of a somatic mutation 28 reported in COSMIC, those not reported in dbSNP databases with a variant allele frequency 29 (VAF) <40-45% but predicted to result in a truncated protein. Single-nucleotide variants 30 (SNVs) were excluded if they had a population frequency of >1% or had a population 31 frequency of <1% but with ethnicity bias and a variant allele frequency (VAF) close to 50%. 32 33 Clinical characteristics were correlated with mutations using Pearson's chi-squared test,

34 Student's t-test and Mann-Whitney U test. NDM were analyzed as individual mutations and

35 mutation groups (e.g. splicing factor, epigenetic) comparing these to patients without these

36 or "wild-type" (e.g. TET2-mutated patients vs. TET2-wild type patients). The impact of

37	specifi	c co-mutations (e.g. patients with TET2 co-mutated with TP53 vs. patients TET2			
38	mutate	ed alone) was not analyzed as the number of events were too small to examine			
39	significant associations. Logistic regression was applied to examine the influence of NDM				
40	on treatment response and adverse event adjusting for JAK2V617F status and treatment as				
41	per tria	al entry (TE) stratification ¹ ; additional adjustment was performed if NDM were found			
42	statisti	cally significant (p<0.05). Median follow-up time calculated using the reverse Kaplan-			
43	Meier method ⁵ with the event of interest reversed. Survival outcomes measured included				
44	overall	survival, transformation-free survival (TFS) and thrombotic/hemorrhagic-free survival			
45	using I	Kaplan-Meier method and log-rank test. Myelofibrosis, leukemia or death were			
46	consid	ered events for TFS calculation. Multivariable analysis of survival outcomes was			
47	perforr	ned using the Cox proportional hazards regression model; including in the model			
48	covaria	ates which had a p-value <0.05 on univariate cox regression analysis. Statistical			
49	analys	es were performed using SPSS version 25 and R statistical software package version			
50	3.4.0 ⁶	with RStudio version 1.1.463. For access to original individual patient clinical data,			
51	please	contact the corresponding author.
