Support Vector Machine Classifier via \( L_{0/1} \) Soft-Margin Loss

Huajun Wang, Yuanhai Shao, Shenglong Zhou, Ce Zhang and Naihua Xiu*

Abstract—Support vector machine (SVM) has attracted great attentions for the last two decades due to its extensive applications, and thus numerous optimization models have been proposed. To distinguish all of them, in this paper, we introduce a new model equipped with an \( L_{0/1} \) soft-margin loss (dubbed as \( L_{0/1} \)-SVM) which well captures the nature of the binary classification. Many of the existing convex/non-convex soft-margin losses can be viewed as a surrogate of the \( L_{0/1} \) soft-margin loss. Despite the discrete nature of \( L_{0/1} \), we manage to establish the existence of global minimizer of the new model as well as revealing the relationship among its minimizers and KKT/P-stationary points. These theoretical properties allow us to take advantage of the alternating direction method of multipliers. In addition, the \( L_{0/1} \)-support vector operator is introduced as a filter to prevent outliers from being support vectors during the training process. Hence, the method is expected to be relatively robust. Finally, numerical experiments demonstrate that our proposed method generates better performance in terms of much shorter computational time with much fewer number of support vectors when against with some other leading methods in areas of SVM. When the data size gets bigger, its advantage becomes more evident.

Index Terms—SVM, \( L_{0/1} \) soft-margin loss, \( L_{0/1} \)-proximal operator, minimizers and KKT/P-stationary points, \( L_{0/1} \)-ADMM.

1 INTRODUCTION

SUPPORT vector machine (SVM) was first introduced by Vapnik and Cortes [1] and then has been widely applied into machine learning, statistic, pattern recognition and so forth. The basic idea is to find a hyperplane in the input space that separates the training data set. In the paper, we consider a binary classification problem that can be described as follows. Suppose we are given a training set \( \{(x_i,y_i)\}_{i=1}^m \), where \( x_i \in \mathbb{R}^n \) are the input vectors and \( y_i \in \{-1,1\} \) are the output labels. The purpose of SVM is to train a hyperplane \( \langle \mathbf{w}, \mathbf{x} \rangle + b = w_1x_1 + \cdots + w_nx_n + b = 0 \) with \( \mathbf{w} \in \mathbb{R}^n \) and \( b \in \mathbb{R} \) by given training set. For any new input vector \( \mathbf{x}' \), we can predict the corresponding label \( y' \) as \( y' = 1 \) if \( \langle \mathbf{w}, \mathbf{x}' \rangle + b > 0 \) and \( y' = -1 \) otherwise. In order to find optimal hyperplane, there are two possible cases: linearly separable and inseparable training data. If the training data is able to be linearly separated in the input space, then the unique optimal hyperplane can be obtained by solving a convex quadratical programming (QP) problem:

\[
\min_{\mathbf{w} \in \mathbb{R}^n, b \in \mathbb{R}} \frac{1}{2} \| \mathbf{w} \|^2 \quad \text{s.t.} \quad y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1, \quad i \in \mathbb{N}_m, \tag{1}
\]

where \( \mathbb{N}_m := \{1, 2, \ldots, m\} \). Here, the \( y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \) provides the distance between the \( i \)th sample and the hyperplane. The above model is termed as hard-margin SVM because it requires correct classifications of all samples. When it comes to the training data that are linearly inseparable in the input space, the popular approach is to allow violations in the satisfaction of the constraints in problem (1) and penalize such violations in the objective function, namely,

\[
\min_{\mathbf{w} \in \mathbb{R}^n, b \in \mathbb{R}} \frac{1}{2} \| \mathbf{w} \|^2 + C \sum_{i=1}^{m} \ell(1 - y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b)), \tag{2}
\]

where \( C > 0 \) is a penalty parameter and \( \ell \) is one of some loss functions that aim at penalizing some incorrectly classified samples and leaving the other ones. Therefore, the above model allows misclassified samples, and thus is known as soft-margin SVM. Clearly, different soft-margin loss functions yield different soft-margin SVM models. Generally speaking, soft-margin loss functions can be summarized as two categories based on the convexity of \( \ell \).

1.1 Convex Soft-Margin Losses

Since there are large numbers of convex soft-margin loss function that have been proposed to deal with the soft-margin SVM problems, we only review some popular ones.

- \textit{Hinge loss function:} \( \ell_{\text{hinge}}(t) = \max\{0, t\}(\forall t \in \mathbb{R}) \). It is non-differentiable at \( t = 0 \) and unbounded. SVM with hinge loss (\( \ell_{\text{hinge}} \)-SVM) was first proposed by Vapnik and Cortes [1], aiming at only penalizing the samples with \( t \geq 0 \).
- \textit{Pinball loss function:} \( \ell_{\text{pinball}}(t) = \max\{t, -\tau t\} \), with \( 0 \leq \tau \leq 1 \), which is still non-differentiable at \( t = 0 \) and unbounded. SVM with this loss function (\( \ell_{\text{pinball}} \)-SVM) was proposed in [2], [3] to pay penalty for all samples. There is a quadratic programming solver embedded in Matlab to solve the SVM with pinball loss function [3].
• Hybrid Huber loss function: \( \ell_{\text{HH}}(t) = \max\{0, t - \tau\} - (\max\{0, \tau/2 - t^2/2\}) + (\max\{0, \tau/2 - t^2/2\}) \) with \( \tau > 0 \). It is differentiable everywhere but still unbounded. This function was first introduced in [4], while SVM with such loss \( \ell_{\text{HH}} \) was first proposed in [5] which can be solved by proximal gradient method [6].

• Square loss function: \( \ell_{\text{square}}(t) = t^2 \), a differentiable but unbounded function. SVM with square loss \( \ell_{\text{square}} \) can be found in [7], [8].

• Some other convex loss functions: the insensitive zone pinball loss [3], the exponential loss function [9] and log loss function [10].

Since those functions are convex, their corresponding SVM models are not difficult to be dealt with. However, the convexity often induces the unboundedness, which removes robustness of those loss functions to outliers from the training data. In order to overcome such drawback, authors in [11], [12] set an upper bound and enforce the loss to stop increasing after a certain extent. Doing so, the original convex loss functions become non-convex.

1.2 Non-Convex Soft-Margin Losses

Again since there are large numbers of non-convex soft-margin losses that have been studied, which is beyond our scope of review, we only present some of them.

• Ramp loss function: \( \ell_{\text{ramp}}^\mu(t) = \max\{0, t - \mu\} \) with \( \mu \geq 0 \), which is non-differentiable at \( t = \mu \) and \( t = 0 \) but bounded between 0 and \( \mu \). It does not penalize the case when \( t < 0 \), while pays linear penalty when \( 0 \leq t \leq \mu \) and a fixed penalty \( \mu \) when \( t > \mu \). This makes this function robust to outliers. Authors in [13] investigated SVM with ramp loss \( \ell_{\text{ramp}} \) SVM.

• Truncated pinball loss function (truncate left side of pinball loss function): \( \ell_{\text{Tpin}}^{\tau,\kappa}(t) = \max\{0, (1 + \tau)t\} - \max\{0, t - \kappa\} \), \( 0 \leq \tau \leq 1 \) and \( \kappa \geq 0 \). It is non-differentiable at \( t = -\kappa \) and \( t = 0 \) and unbounded. The penalty is fixed at \( \kappa \) for \( t < -\kappa \) and is linear otherwise. SVM with such loss \( \ell_{\text{Tpin}} \) can be referred in [14].

• Asymmetrical truncated pinball loss function (truncate two side of pinball loss function): \( \ell_{\text{ATpin}}^{\tau,\kappa}(t) = \max\{0, (1 + \tau)t\} - \max\{0, t + \kappa\} \) with \( 0 \leq \tau \leq 1 \) and \( \kappa \geq 0 \). This function is non-differentiable at \( t = -\kappa \) but bounded between 0 and \( \max\{\kappa, \mu\} \). The penalty is fixed at \( \kappa \) for \( t < -\kappa \) and at \( \mu \) for \( t > \mu \) but is linear otherwise.

SVM with such loss \( \ell_{\text{ATpin}} \) was investigated in [15].

• Sigmoid loss function: \( \ell_{\text{sigmoid}}(t) = 1/(1 + \exp(-t)) \), a differentiable and bounded (between 0 and 1) function. It penalizes all samples. SVM with this loss \( \ell_{\text{sigmoid}} \) can be seen in [16].

• Some other non-convex loss function: normalized sigmoid cost loss function [17].

Compared with convex soft-margin loss, most of non-convex loss functions are less sensitive to feature noises or outliers due to their boundedness. Apparently, non-convexity would lead to difficulties to computations in terms of solving corresponding SVM models. In summary, the basic principles to choose a soft-margin loss are three aspects[18], [19]: (i) It is able to capture the discrete nature of the binary classification. (ii) It is suggested to be bounded to be robust to feature noises or outliers. (iii) It makes itself based SVM model easy to be computed.

1.3 \( \ell_{0/1} \) Soft-Margin Loss

Taking above principles into consideration, we now introduce the 0-1 \( \ell_{0/1} \) soft-margin loss defined as

\[
\ell_{0/1}(t) = \begin{cases} 
1, & t > 0, \\
0, & t \leq 0.
\end{cases}
\]

The \( \ell_{0/1} \) soft-margin loss function is the most nature loss function for binary classification[20], [21]. Its properties are summarized as below.

• (i) It is discontinuous at \( t = 0 \), which captures the discrete nature of the binary classification (correctness or incorrectness) [22].

• (ii) It is lower semi-continuous and nonconvex by the definition in [23]. Since it is either 0 or 1, sparsity and robustness will be guaranteed. In fact, it does not count the number of samples with \( t < 0 \), which leads to sparsity, while returns 1 otherwise, which ensures robustness to outliers.

• (iii) It is differentiable everywhere but at \( t = 0 \). However, it has subdifferential

\[
\partial \ell_{0/1}(0) = \mathbb{R}_+ := \{ t \in \mathbb{R} : t \geq 0 \}
\]

and zero gradients elsewhere, see Lemma 2.1, which makes the computation tractable.

1.4 \( \ell_{0/1} \)-SVM

For the sake of easing the reading, we present some notations here. Let \( \|\mathbf{x}\| \) and \( \|\mathbf{x}\|_0 \) be the Euclidean norm and the zero norm of \( \mathbf{x} \) that counts the number of non-zero elements of \( \mathbf{x} \). Denote \( A := \text{Diag}(y)X^\top \) with \( X = [x_1, x_2, \ldots, x_m] \in \mathbb{R}^{n \times m} \) and \( y = (y_1, y_2, \ldots, y_m) \in \mathbb{R}^m \), where \( \text{Diag}(y) \) is a diagonal matrix with diagonal elements being elements in \( y \).

For a positive integer \( m \) and a vector \( \mathbf{u} \in \mathbb{R}^m \), denote

\[
\mathbb{N}_m := \{1, 2, \ldots, m\}, \quad 1 := (1, 1, \ldots, 1)^\top \in \mathbb{R}^m, \quad \mathbb{R}_+^m := \{\mathbf{u} \in \mathbb{R}^m : u_i \geq 0, i \in \mathbb{N}_m\}, \quad |\mathbf{u}| := (|u_1|, \ldots, |u_m|)^\top, \quad \mathbf{u}_+ := (\max\{u_1, 0\}, \ldots, \max\{u_m, 0\})^\top.
\]

These notations indicate

\[
L_{0/1}(\mathbf{u}) := \|\mathbf{u}_+\|_0 = \sum_{i=1}^m l_{0/1}(u_i),
\]

which returns the number of all positive elements in \( \mathbf{u} \). We call (3) the \( L_{0/1} \) soft-margin loss. Now, replacing \( \ell \) by \( \ell_{0/1} \) in (2) and using above notations allow us to rewrite model (2) in a matrix form,

\[
\min_{\mathbf{w} \in \mathbb{R}^n, b \in \mathbb{R}} f(\mathbf{w}; b) := \frac{1}{2} \|\mathbf{w}\|^2 + C(1 - (A\mathbf{w} + b)y)_{+} + \|\mathbf{0}. \]

We call this model \( \ell_{0/1} \)-SVM. The objective function \( f \) is lower semicontinuous, non-differentiable and non-convex.
It is difficult to be solved directly by most existing optimization algorithms. Despite that the discrete nature of zero norm makes above model NP-hard to be solved, the $L_{0/1}$-SVM model is an ideal SVM model because it guarantees as few misclassified as possible for binary classification. Therefore, we carry out this paper along with this model.

1.5 Contributions

In this paper, we start to study the theoretical properties of the $L_{0/1}$-SVM model and then design a new efficient and robust algorithm to solve the model. The main contributions of the paper can be summarized as follows.

(i) We prove the existence of a global minimizer of $L_{0/1}$-SVM, which has not been thoroughly studied in prior works. Based on the explicit expressions of subdifferential and proximal operator of the $L_{0/1}$ loss (3), we introduce two types of optimality conditions of the problem: KKT and P-stationary points. We then unravel the relationships among a global/local minimizer and the KKT/P-stationary points. This result is essential to our algorithmic design later on.

(ii) We adopt the famous alternating direction method of multipliers (ADMM) to solve the $L_{0/1}$-SVM problem, and thus the method is dubbed as $L_{0/1}$ADMM. We show that if the sequence generated by the proposed method converges, then it must converge to a P-stationary points. To the best of our knowledge, it is the first time that a method being created aims at solving (4) directly rather than its surrogate model (2). The novelty of the method is using the $L_{0/1}$-support vector operator as a filter to prevent the outliers from being support vectors during training process.

(iii) We compare $L_{0/1}$ADMM with four other existing leading methods on solving SVM problems with synthetic and real data sets. Extensive numerical experiments demonstrate that our proposed method achieves better performance in terms of providing higher prediction accuracy, using a small number of support vectors and consuming shorter computational time.

This paper is organized as follows. In Section 2, we will give the explicit expressions of three subdifferentials of $L_{0/1}$ soft-margin loss and derive its proximal operator. Section 3 presents the main theoretical contributions. We will show the existence of a global minimizer to problem (4) as well as investigating the relationships among a global/local minimizer and the KKT/P-stationary points of $L_{0/1}$-SVM problem. In Section 4, we will introduce the $L_{0/1}$-support vector operator and design the algorithm based on the optimality conditions established in previous section. Numerical experiments including comparison with other solvers and concluding remarks are given in the last two sections.

2 Subdifferential and Proximal Operator

To well analyze the properties of the $L_{0/1}$ soft-margin loss, we need introduce the necessary background of the subdifferential and the proximal operator of the $||u||_0$.

2.1 $L_{0/1}$ Subdifferential

From [24, Definition 8.3], for a proper and lower semicontinuous function $f : \mathbb{R}^m \rightarrow \mathbb{R}$, the regular, limiting and horizon subdifferentials are defined respectively as

$$\hat{\partial}f(u) = \left\{ v \in \mathbb{R}^m : \liminf_{z \rightarrow u} \frac{f(z) - f(u) - \langle v, z-u \rangle}{\|z-u\|} \geq 0 \right\},$$

$$\partial f(u) = \limsup_{z \rightarrow u} \hat{\partial}f(z) = \left\{ v \in \mathbb{R}^m : \exists z_j \rightarrow u, v_j \in \hat{\partial}f(z_j) \right\},$$

$$\partial^\infty f(u) = \limsup_{\sigma \downarrow 0, z \rightarrow u} \sigma \partial \hat{\partial}f(z) = \left\{ v \in \mathbb{R}^m : \exists z_j \rightarrow u, v_j \in \hat{\partial}f(z_j) \right\},$$

where $\sigma \downarrow 0$ means $\sigma > 0$ and $\sigma \rightarrow 0$, and $z \rightarrow u$ means both $z \rightarrow u$ and $f(z) \rightarrow f(u)$. If the function $f$ is convex, then the limiting subdifferential is also known to the subgradient.

**Lemma 2.1.** The regular, limiting and horizon subdifferentials of $||u||_0$ at $u$ enjoy following property,

$$\Omega(u) := \hat{\partial}||u||_0 = \partial||u||_0 = \partial^\infty||u||_0$$

$$= \left\{ v \in \mathbb{R}^m : v_i \begin{cases} \geq 0, & u_i = 0, \\ = 0, & u_i \neq 0, \end{cases}, i \in \mathbb{N}_m \right\}.$$  

We use a simple example to illustrate the three subdifferentials of $||u||_0$. Consider one dimensional case $m = 1$. As shown in Figure 1, the red lines denote some elements in $\partial||0||_0 = \partial\ell_{0/1}(0)$. In fact, all right slashes crossing the origin comprise of the subdifferential $\partial||0||_0$.

![Fig. 1: The $\ell_{0/1}$ soft-margin loss function. The blue line (including the blue original) is the function value and the red lines are two of subdifferentials in $\partial\ell_{0/1}(0)$.

Our next result is about $L_{0/1}$ Proximal operator, which will be very useful in designing the algorithm in Section 4.

2.2 $L_{0/1}$ Proximal Operator

By [25, Definition 12.23], the proximal operator of $f : \mathbb{R} \rightarrow \mathbb{R}$, associated with a parameter $\alpha > 0$, at point $s \in \mathbb{R}$, is defined by

$$\text{Prox}_\alpha f(s) = \arg \min_{u \in \mathbb{R}} \alpha f(u) + \frac{1}{2}(u-s)^2.$$  

The following lemma states that the proximal operator admits a closed form solution when $f = \ell_{0/1}$.
Lemma 2.2 (One-dimensional case). For an $\alpha > 0$, the proximal operator of $\ell_{0/1}()$ at $s$ is given by

$$\text{Prox}_{\alpha \ell_{0/1}}(s) := \begin{cases} 0, & 0 \leq s < \sqrt{2\alpha}, \\ 0 \text{ or } s, & s = \sqrt{2\alpha}, \\ s, & s > \sqrt{2\alpha} \text{ or } s < 0. \end{cases} (7)$$

It is worth mentioning that the proximal operator may not be unique if $s = \sqrt{2\alpha}$ in (7). However, to guarantee the uniqueness, hereafter, we always choose the proximal operator to be zero if it is not unique. Because of this, the proximal operator of $\ell_{0/1}$ is rewritten as

$$\text{Prox}_{\alpha \ell_{0/1}}(s) = \begin{cases} 0, & 0 \leq s \leq \sqrt{2\alpha}, \\ s, & \text{otherwise}. \end{cases} (8)$$

The proximal operator of $\ell_{0/1}$ is shown in Figure 2, where the red line denotes the proximal operator.

Based on the one dimensional case, we could derive the proximal operator of $L_{0/1}(\cdot) = \|\cdot\|_0$. The proof is similar to that of Lemma 2.2 and thus is omitted.

Lemma 2.3 (Multi-dimensional case). For an $\alpha > 0$, the proximal operator of $L_{0/1}$ at $s \in \mathbb{R}^m$ is given by

$$\text{Prox}_{\alpha L_{0/1}}(s) := \begin{bmatrix} \text{Prox}_{\alpha \ell_{0/1}}(s_1) \\ \vdots \\ \text{Prox}_{\alpha \ell_{0/1}}(s_m) \end{bmatrix}. \quad (9)$$

To proceed further, we consider the following problem

$$\min_{u \in \mathbb{R}^m} f_C(u) := h(u) + C\|u_+\|_0, \quad (10)$$

where $h : u \rightarrow \mathbb{R}$ is a smooth convex function and gradient Lipschitz continuous with a Lipschitz constant $\tau_h > 0$ and $C > 0$ is given. To see the global solution of above problem, same as [26], we introduce an auxiliary problem,

$$\min_{u \in \mathbb{R}^m} f_\gamma(u, z) := C\|u_+\|_0 + h(z) \quad (11)$$

+ $\langle \nabla h(z), u - z \rangle + \frac{1}{2\gamma}\|u - z\|^2,$

for some $\gamma > 0$ and fixed $z \in \mathbb{R}^m$, where $\nabla h$ is the gradient of $h$. This problem allows us to acquire the result related to the proximal operator of $L_{0/1}$.

Lemma 2.4. For any given $C > 0$, we have following results.

(i) If $u^*$ is the global optimal solution to (11) for any fixed $\gamma > 0$ and $z \in \mathbb{R}^m$, then it holds

$$u^* = \text{prox}_{\gamma C L_{0/1}}(z - \gamma \nabla h(z)).$$

(ii) If $u^*$ is a global optimal solution to (10), then it is also a global optimal solution to (11) with $z = u^*$ and $0 < \gamma \leq 1/\tau_h$, namely,

$$f_C(u^*) = f_\gamma(u^*, u^*) \leq f_\gamma(u, u^*), \quad \forall u \in \mathbb{R}^m.$$
**Definition 3.1 (KKT point of (13)).** For a given \( C > 0 \), we say that \((w^*; b^*; u^*)\) is a KKT point of problem (13) if there is a multiplier vector \( \lambda^* \in \mathbb{R}^m \) such that

\[
\begin{align*}
    w^* + A^T \lambda^* &= 0, \\
    \langle y, \lambda^* \rangle &= 0, \\
    u^* + Aw^* + b^* y &= 1, \\
    C \partial \| u^* \|_0 + \lambda^* &\geq 0.
\end{align*}
\] (15)

The following result reveals the relationship between a local minimizer and a KKT point of (13).

**Theorem 3.2.** For a given \( C > 0 \), then \((w^*; b^*; u^*)\) is a KKT point of (13) if and only if it is a KKT point.

Now let us define some notation

\[
B := [A \ y] \in \mathbb{R}^{m \times (n+1)}, \quad H := \begin{bmatrix} I_{n \times n} & 0 \\ 0 & 0 \end{bmatrix} B^+,
\] (16)

where \( B^+ \) is the generalized inverse of \( B \). These notations could equivalently rewrite (13) as

\[
\min_{u \in \mathbb{R}^m} \frac{1}{2} \| H(u - 1) \|^2 + C\| u_+ \|_0,
\] (17)

which is an unconstrained non-convex optimization problem. Based on (17), we will derive the proximal stationary point of (13), and this point is useful as a stop criteria of our algorithm proposed later.

**Definition 3.2 (P-stationary point of (13)).** For a given \( C > 0 \), we say \((w^*; b^*; u^*)\) is a proximal stationary (P-stationary) point of problem (13) if there is a multiplier vector \( \lambda^* \in \mathbb{R}^m \) and constant \( \gamma > 0 \) such that

\[
\begin{align*}
    w^* + A^T \lambda^* &= 0, \\
    \langle y, \lambda^* \rangle &= 0, \\
    u^* + Aw^* + b^* y &= 1, \\
    \text{prox}_{\gamma C\| \cdot \|_0}(u^* - \gamma \lambda^*) &= u^*.
\end{align*}
\] (18)

We now reveal the relationship between a global minimizer and a P-stationary point of (13). Before which, let

\[
\gamma_H := 1/\lambda_{\text{max}}(H^T H),
\]

where \( \lambda_{\text{max}}(H^T H) \) denotes maximum eigenvalue of \( H^T H \).

**Theorem 3.3.** Assume \( B \) has a full column rank. For a given \( C > 0 \), if \((w^*; b^*; u^*)\) is a global minimizer of (13) then it is a P-stationary point with \( 0 < \gamma \leq \gamma_H \).

Note that \( B \) having a full column rank means \( m \geq n \). However, numerical experiments will demonstrate that our proposed algorithm also works for the cases of \( m < n \) in terms of finding a P-stationary point. To end this section, we also unravel the relationship between a P-stationary point and a KKT point of (13).

**Theorem 3.4.** For a given \( C > 0 \), if \((w^*; b^*; u^*)\) is a P-stationary point with \( 0 < \gamma \leq \gamma_H \) of (13), then it is also KKT point.

The above two theorems state that a global minimizer of (13) is a P-stationary point which is also a KKT point. Most importantly, we could use the P-stationary point as a termination rule in terms of guaranteeing the local optimality of a point generated by the algorithm proposed in next section.

### 4. ALGORITHMIC DESIGN

In this section, we introduce the concept of \( L_{0/1} \)-support vector operator and describe how ADMM can be applied into solving the \( L_{0/1} \)-SVM problem (13).

#### 4.1 \( L_{0/1} \)-Support Vector Operator

In SVMs, the optimal hyperplane is actually only determined by a small portion of training samples. These samples are called support vectors. It is well known that soft-margin loss functions at non-support vectors have zero subdifferentials [13], [14], [28], [29]. In other words, to select support vectors, one could find samples at which the loss function has nonzero subdifferentials. However, this approach is not suitable for \( L_{0/1} \) soft-margin loss, since \( \partial \ell_{0/1}(0) = \mathbb{R}^+ \) and \( \partial \ell_{0/1}(t) = \{0\} \) elsewhere. This indicates samples with \( u_i = 1 - y_i(\langle w, x_i \rangle + b) \neq 0 \) always have zero subdifferentials and samples with \( u_i = 0 \) also have zero subdifferentials due to \( 0 \in \mathbb{R}_+ \), which probably leads to empty set of support vectors. To overcome such drawback, we introduce a novel selection scheme, \( L_{0/1} \)-support vectors operator, to choose samples to be support vectors.

**Definition 4.1 (\( L_{0/1} \)-support vector operator).** For a given \( \alpha > 0 \), the \( L_{0/1} \)-support vector operator is defined by

\[
T_{\alpha}(z) := \left\{ i \in \mathbb{N}_m : \text{prox}_{\alpha L_{0/1}}(z)_i = 0 \right\}.
\] (19)

Hereafter, we let \( z_T \) (resp. \( A_T \)) be the sub-vector (resp. sub-matrix) contains elements of \( z \) (resp. rows of \( A \)) indexed on \( T \). Let \( T := T_{\alpha}(z) \) and its complementarity set be \( T^c := \mathbb{N}_m \setminus T \). It follows from Definition 4.1 and (8) that

\[
\begin{bmatrix}
    (\text{prox}_{\alpha L_{0/1}}(z))_T \\
    (\text{prox}_{\alpha L_{0/1}}(z))_{T^c}
\end{bmatrix}
= \begin{bmatrix}
    0 \\
    z_{T^c}
\end{bmatrix}.
\]

This leads to

\[
\mathbf{u} = \text{prox}_{\alpha L_{0/1}}(z) \iff \begin{bmatrix}
    u_T \\
    u_{T^c} - z_{T^c}
\end{bmatrix} = 0.
\] (20)

The above equivalence will help us to design the algorithm that we are ready to outline as below.

#### 4.2 Framework of ADMM

The augmented Lagrangian function associated with the model (13) can be written as

\[
L_\sigma(w, b, u, \lambda) = \frac{1}{2} \| w \|^2 + C\| u_+ \|_0 + \langle \lambda, \varpi \rangle + \frac{\sigma}{2} \| \varpi \|^2,
\] (21)

where \( \lambda \) is Lagrangian multiplier, \( \sigma > 0 \) is a given parameter and

\[
\varpi := u + Aw + by - 1.
\]

We take advantage of the ADMM to solve the augmented Lagrangian function. Given the \( k \)th iteration \((w^k, b^k, u^k, \lambda^k)\), its framework takes the following form

\[
\begin{align*}
    w^{k+1} &= \arg\min_{w \in \mathbb{R}^n} L_\sigma(w^k, b^k, u^k, \lambda^k), \\
    w^{k+1} &= \arg\min_{w \in \mathbb{R}^n} L_\sigma(w^k, b^k, u^{k+1}, \lambda^k) + \frac{\sigma}{2} \| w - w^k \|^2, \\
    b^{k+1} &= \arg\min_{b \in \mathbb{R}^n} L_\sigma(w^{k+1}, b, u^{k+1}, \lambda^k), \\
    u^{k+1} &= \lambda^k + \eta \sigma \varpi^{k+1}.
\end{align*}
\]
where \( \eta > 0 \) is referred as the dual step size and \( \omega^{k+1} := u^{k+1} + Aw^{k+1} + b^{k+1}y - 1 \). Here, 
\[
\| w - w^k \|_D^2 = \langle w - w^k, D_k (w - w^k) \rangle
\]
is the so-called proximal term and \( D_k \in \mathbb{R}^{n \times n} \) is symmetric. Note that if \( D_k \) is positive semidefinite, then the above framework is the standard semi-proximal ADMM [30]. However, authors in papers [31]–[33] have also investigated ADMM with the indefinite proximal terms, namely \( D_k \) is indefinite. The basic principle of choosing \( D_k \) is to guarantee the convexity of \( w \)-subproblem of (22). Since \( L_{\sigma}(w, b^k, u^{k+1}, \lambda^k) \) here is strongly convex with respect to \( w, D_k \) is able to be chosen as a negative semidefinite matrix. The flexibility of selecting \( D_k \) allows us to design a very efficient algorithm when support vectors are used.

4.3 \( L_{0/1} \) ADMM

We mainly describe how each subproblem of (22) can be addressed efficiently as well as how the support vectors can be applied into reducing the computational cost.

(i) Updating \( u^{k+1} \). By (19), we denote
\[
z^k := 1 - Aw^k - b^k y - \lambda / \sigma, \quad T_k := T^{C/\sigma}(z^k).
\]
Then the \( u \)-subproblem of (22) is reformulated as
\[
\begin{align*}
u^{k+1} &= \text{argmin}_{u \in \mathbb{R}^m} C[u, \|0 + \sigma/2\| u - z^k\|^2]. \\
&= \text{Prox}_C^\sigma_{L_{0/1}}(z^k),
\end{align*}
\]
which combined (20) results in
\[
u_{T_k}^{k+1} = 0, \quad u_{T_k}^{k+1} = z_{T_k}^k.
\]

(ii) Updating \( w^{k+1} \). We always choose 
\[
D_k = -A_{T_k}^TA_{T_k},
\]
which enables us to derive the \( w \)-subproblem of (22) as
\[
\begin{align*}
w^{k+1} &= \text{argmin}_{w \in \mathbb{R}^n} \frac{1}{2} \| w \|^2 + \frac{\sigma}{2} \| Aw - v^k \|^2 + \\
&\quad \frac{\sigma}{2} \| w - w^k \|^2 - A_{T_k}^TA_{T_k}.
\end{align*}
\]
\[
\begin{align*}
&= \text{argmin}_{w \in \mathbb{R}^n} \frac{1}{2} \| w \|^2 + \frac{\sigma}{2} \| Aw - v^k \|^2 - \\
&\quad \frac{\sigma}{2} \| A_{T_k} w - A_{T_k} w^k \|^2,
\end{align*}
\]
where \( v^k := -(u^{k+1} + b^k y - 1 + \lambda / \sigma) \). Moreover,
\[
\begin{align*}
v_{T_k}^{k+1} &= -(u_{T_k}^{k+1} + b^k y_{T_k} - 1 + \lambda_{T_k}^k / \sigma) \\
&= -(u_{T_k}^k + b^k y_{T_k} - 1 + \lambda_{T_k}^k / \sigma) \\
&= A_{T_k} w^k,
\end{align*}
\]
where the second and third equation are from (24) and (23). Now we rewrite (26) as
\[
\begin{align*}
w^{k+1} &= \text{argmin}_{w \in \mathbb{R}^n} \frac{1}{2} \| w \|^2 + \frac{\sigma}{2} \| Aw - v^k \|^2 - \\
&\quad \frac{\sigma}{2} \| A_{T_k} w - v_{T_k}^k \|^2
\end{align*}
\]
\[
= \text{argmin}_{w \in \mathbb{R}^n} \frac{1}{2} \| w \|^2 + \frac{\sigma}{2} \| A_{T_k} w - v_{T_k}^k \|^2.
\]
To solve (27), we need find the solution to the equation
\[
(I + \sigma A_{T_k}^T A_{T_k}) w = \sigma A_{T_k}^T v_{T_k}.
\]
Note that \( A_{T_k} \in \mathbb{R}^{|T_k| \times n} \), where \(|T_k|\) is the cardinality of \( T_k \).
Then (28) can be addressed efficiently by following rules:

- If \( n \leq |T_k| \), one could just solve (28) through
  \[
  w^{k+1} = \sigma P_{k}^{-1} A_{T_k}^T v_{T_k}.
  \]
- If \( n > |T_k| \), the matrix inverse lemma enables us to calculate the inverse as
  \[
  P_{k}^{-1} = I - \sigma A_{T_k}^T (I + \sigma A_{T_k} A_{T_k})^{-1} A_{T_k}.
  \]

Then we update \( w^{k+1} \) as
\[
\begin{align*}
w^{k+1} &= \sigma A_{T_k}^T v_{T_k} - \sigma A_{T_k}^T Q_k^{-1} A_{T_k} A_{T_k} v_{T_k} \\
&= \sigma A_{T_k}^T v_{T_k} - \sigma A_{T_k}^T Q_k^{-1} (Q_k - I) v_{T_k} \\
&= \sigma A_{T_k}^T Q_k^{-1} v_{T_k}.
\end{align*}
\]

(iii) Updating \( b^{k+1} \). Letting \( r^k := -(Aw^{k+1} - 1 + u^{k+1} + \lambda / \sigma) \), it follows from \( b \)-subproblem in (22) that
\[
\begin{align*}
b^{k+1} &= \text{argmin}_{b \in \mathbb{R}} \frac{\sigma}{2} \| u^{k+1} - 1 + Aw^{k+1} + by \|^2 + \langle \lambda^k, by \rangle \\
&= \text{argmin}_{b \in \mathbb{R}} \frac{\sigma}{2} \| by - r^k \|^2, \\
&= \langle y, r^k \rangle / \| y \|^2 = \langle y, r^k \rangle / m.
\end{align*}
\]

(iv) Updating \( \lambda^{k+1} \). According to (15) and Lemma 2.1, \( \lambda \) and \( u \) have the relation \(-A \in \mathbb{C} \| u \|_o\), namely \( \lambda_1 = 0 \) if \( u_i \neq 0 \). Based on this, we update the Lagrangian multiplier \( \lambda^{k+1} \) in the following way:
\[
\begin{align*}
\lambda_{T_k}^{k+1} &= \lambda_{T_k}^k + \eta \sigma \omega^{k+1}, \\
\lambda_{T_k}^{k+1} &= 0.
\end{align*}
\]

We now summarize the framework of the algorithm in Algorithm 1. We call the method \( L_{0/1} \) ADMM, an abbreviation for \( L_{0/1} \)-SVM solved by ADMM.

**Algorithm 1 : \( L_{0/1} \) ADMM for solving problem (4)**

Initialize \( (w^0, b^0, u^0, \lambda^0) \). Choose parameters \( C, \sigma, K > 0 \) and set \( k = 0 \).

while The halting condition does not hold and \( k \leq K \) do

- Update \( T_k := T^{C/\sigma}(z^k) \) as in (23).
- Update \( u^{k+1} \) by (24).
- Update \( w^{k+1} \) by (29) if \( n \leq |T_k| \) and by (31) otherwise.
- Update \( b^{k+1} \) by (32).
- Update \( \lambda^{k+1} \) by (33).
- Set \( k = k + 1 \).
end while

return the final solution \( (w^k, b^k) \) to (4).

**Remark 4.1.** We have some comments on Algorithm 1 regarding to the computational complexity. Note that in each step, updating \( w^{k+1} \) dominates the whole computation, which needs solve a linear equation system (28) through (29) or (31). If \( n \leq |T_k| \), then the computational complexities of calculating \( A_{T_k}^T A_{T_k} \) and \( P_{k}^{-1} \) are
\( O(n^2 |T_k|) \) and \( O(n^\kappa) \) with \( \kappa \in (2,3) \), respectively. If \( n > |T_k| \), then the computational complexities of calculating \( A_T, A_T^T \), and \( Q_C^{-1} \) are \( O(n^2 |T_k|^2) \) and \( O(|T_k|^\kappa) \) with \( \kappa \in (2,3) \), respectively. Overall the whole complexity in each step is \( O(\min\{n^2, |T_k|^2\} \max\{n, |T_k|\}) \). Therefore, if there are few number of \( L_{0/1} \) support vectors, namely \( |T_k| \) is very small, then the complexity is very low, which allows us to do large scale computations.

The following theorem shows that if the sequence generated by \( L_{0/1} \) converges, then it must converge to a \( P \)-stationary point of (13).

**Theorem 4.1.** Let \( (w^*, b^*, u^*, \lambda^*) \) be the limit point of the sequence \( \{(w^k, b^k, u^k, \lambda^k)\} \) generated by \( L_{0/1} \). Then \( (w^*, b^*, u^*) \) is a \( P \)-stationary point of problem (13) where \( \gamma = 1 / \sigma \).

**Remark 4.2.** The convergence result in above theorem is best result that we expect since (13) is non-convex and discrete. Establishment of convergence property of ADMM to address such kind of problem is a very challenging task for recent decades. There are a few publications that aim at studying ADMM to solve non-convex optimization problems while the established convergence results always rely on heavy assumptions. Importantly, Theorem 4.1 allows us to take advantage of the \( P \)-stationary point as a stopping criteria. In fact, we will terminate the algorithm if the point \( (w^k, b^k, u^k, \lambda^k) \) closely satisfies the conditions in (18), namely,

\[
\max\{\theta_1^k, \theta_2^k, \theta_3^k, \theta_4^k\} < \text{tol},
\]

where \( \text{tol} \) is the tolerance level and

\[
\theta_1^k := \frac{\|w^k + A_T^T \lambda^k_T\|}{1 + \|w^k\|}, \quad \theta_2^k := \frac{|(y_{T_k}, \lambda^k_{T_k})|}{1 + |T_k|},
\]

\[
\theta_3^k := \frac{\|u^k - b\|}{\sqrt{m}}, \quad \theta_4^k := \frac{\|u^k - \prox_{C/\sigma L_{0/1}}(u^k - \lambda^k/\sigma)\|}{1 + \|u^k\|}.
\]

5 Numerical Experiments

In this part, we will conduct extensive numerical experiments to show sparsity, robustness and effectiveness of our algorithm \( L_{0/1} \) by using MATLAB (2017a) on a laptop of 32GB of memory and Inter Core i7 2.7Ghz CPU, against four leading methods both on synthetic data and real data.

(a) Parameters setting. In our algorithm, the parameters \( C \) and \( \sigma \) control the number of support vectors, see (23), so choosing a good value of these two parameters is crucial. The standard 10-fold cross validation is employed in training set to choose optimal parameters, where the parameters \( C \) and \( \sigma \) are both selected from the candidate values \( \{a^{-7}, a^{-6}, \ldots, a^7\} \) with \( a = \sqrt{2} \). The parameters with highest cross validation accuracy are picked out. In addition, we set \( \eta = 1.618 \). For the initial points, \( w^0 = 0.01 \times 1 \), \( b^0 = 0 \) and \( u^0 = \lambda^0 = 0 \). Finally, the maximum iteration number is \( K = 10^4 \) and the tolerance level is set as \( \text{tol} = 10^{-5} \) on synthetic data and \( \text{tol} = 10^{-3} \) on real data.

(b) Benchmark methods. Four leading methods are introduced to make comparisons. All their parameters are optimized to maximize the accuracy by 10-fold cross validation in each training set.

SSVM SVM with square soft-margin loss \([7]\) is implemented by LibSVM \([34]\), where the parameter \( C \) is selected from the set \( \{2^{-7}, 2^{-6}, \ldots, 2^7\} = : \Omega \).

FSVM SVM with pinball soft-margin loss can be achieved by using the traversal algorithm \([36]\), where \( C \) and \( \tau \) are turned from the candidate values \( \{0.1, 0.5, 1, 5, 10\} \cup \Omega \) and \( \{-1, -0.99, \ldots, 0.99\} \), respectively \([36]\). In order to improve computational efficiency of the traversal algorithm, authors in \([36]\) suggested \( \tau = 0 \) (i.e., HSVM) when the number of training data is large.

R SVM SVM with ramp soft-margin loss can be achieved by employing the \( \text{CCCP} [37] \), where the parameters \( C \) and \( \mu \) are selected from \( \Omega \) and \( \{0.1, 0.2, \ldots, 1\} \).

(c) Evaluation criteria. For the evaluation of classification performances, we report three evaluation criterions of five methods, that is, accuracy \((\text{ACC})\), number of support vectors \((\text{NSV})\) and CPU time \((\text{CPU})\). Let \( \{x_j^{\text{test}}, y_j^{\text{test}}\}_{j=1}^{m_t} \) be \( m_t \) test samples data. The testing accuracy is defined by

\[
\text{ACC} := 1 - \frac{1}{2m_t} \sum_{j=1}^{m_t} \text{sign}(\langle w, x_j^{\text{test}} \rangle + b) - y_j^{\text{test}},
\]

where \( \text{sign}(\pi) = 1 \) if \( \pi > 0 \) and \( \text{sign}(\pi) = -1 \) otherwise, \((w, b)\) is obtained by each method. The accuracy measures the ability of a model/method to correctly predict the class labels of any new input vectors. The higher the value of \( \text{ACC} \) is, the better the model/method is. The \( \text{NSV} \) and \( \text{CPU} \) are two comprehensive measures for classification models. The smaller their values are, the better the model is.

5.1 Comparisons with Synthetic Data

In this subsection, we first show that \( L_{0/1} \) has the ability of support vector selection. For visualization, we consider a two-dimensional example where the features come from Gaussian distributions used in \([3], [36]\).

Example 5.1 (Synthetic data in \( \mathbb{R}^2 \) without outliers). In this example, \( m \) samples \( x_i \) with positive labels \( y_i = +1 \) are drawn from \( N(\mu_1, \Sigma_1) \) and samples \( x_i \) with negative labels \( y_i = -1 \) are drawn from \( N(\mu_2, \Sigma_2) \), where \( \mu_1 = [0.5, -3]^\top, \mu_2 = [-0.5, 3]^\top \) and \( \Sigma_1 = \Sigma_2 = \text{Diag}(0.2, 3) \). We generate \( m \) samples with two classes having equal numbers, and then evenly split all samples into a training set and a testing set.

Data generated in this way has centralized features of each class. For this experiment, the corresponding Bayes classifier is \( x_2 = 2.5x_1 \). We display Bayes classifier and 100 training data for each class in Figure 3 (a), where samples are able to be linearly separated and no extra noises contaminate the samples. We then add outliers on data generated in Example 5.1 as follows.

Example 5.2 (Synthetic data in \( \mathbb{R}^2 \) with outliers). Firstly, \( m \) samples with two classes having equal numbers are generated as in Example 5.1. Then in each class, we
randomly flip r percentage of labels. For instance, in m/2 samples with positive labels +1, we change mr/2 labels of them to −1. This means r percentage of m samples are flipped their labels, namely rm outliers are generated. Finally, we again evenly split those samples into a training set and a testing set. In Figure 3 (b), one training set with r=10% outliers are produced.

Fig. 3: Blue stars: sampling points in class −1. Red crosses: sampling points in class +1. Red dashed lines: the Bayes classifier. (a) A two dimensions training set with m = 200 samples. (b) Data in (a) but with r=10% outliers.

To solve these two examples, five methods are applied to calculate the classification boundary $x_2 = w_1 x_1 + b$. Since data are generated randomly, we repeat above process 10 times to avoid randomness and report average results of ACC, NSV and CPU.

(d) Synthetic data without outliers. We first compare five methods for solving Example 5.1, where m ∈ {4000, 8000, · · · , 20000}. Average results are reported in Table 1. It can be clearly seen that all methods achieved desirable ACC and $L_{0/1}\text{ADMM}$ got slightly better ones. When it comes to NSV, the picture is significant different. $L_{0/1}\text{ADMM}$ used a very small portion of samples as the support vectors, while $SSVM$ and $PSVM$ used all samples. Therefore, the phenomenon manifests that our constructed $L_{0/1}$ support vector operator is very effective to choose informative samples as the support vectors. As we mentioned in Remark 4.1, a small portion of samples used will greatly speed up the computation. This is testified by very short CPU time taken by $L_{0/1}\text{ADMM}$. Apparently, $PSVM$ and $RSVM$ consumed much longer time, which indicates these two methods would suffer from computational slowness in large scale date settings.

(e) Synthetic data with outliers. In the following experiment, we test five methods for solving Example 5.2, with fixing $m = 10000$, $n = 2$, $r \in \{0, 0.05, 0.1, 0.15, 0.2\}$. Average results are presented in Table 2. Again, there is no big difference of ACC generated by five methods. When more outliers were added, ACC became smaller. In addition, $L_{0/1}\text{ADMM}$ got slightly better ACC, which means it is more robust to outliers than other methods. As for NSV, $SSVM$ and $PSVM$ again took all samples. Compared with solving Example 5.1, $HSVM$ this time used more support vectors and NSV increased when more outliers added, which means it is sensitive to the outliers. By contrast $L_{0/1}\text{ADMM}$ and $RSVM$ seem to be more robust to the outliers since NSVs did not vary greatly with r altering. Interestingly, being different with $HSVM$, these two methods needed fewer support vectors when more outliers added. Finally, $L_{0/1}\text{ADMM}$ always ran the fastest, with only taking less than 0.01 seconds, followed by $HSVM$ and $SSVM$. Same as solving such data without outliers, $PSVM$ consumed quite long CPU time. This implies that it may suffer from severe computational slowness for data with large size.

### 5.2 Comparisons with Real Data

We now focus on applying five methods into solving 13 real data sets. Table 3 presents the detailed information of them, where the last five ones have the training and testing data.

Example 5.3 (Real data without outliers). We perform 10-fold cross validation for the first six data sets, where each data is randomly split into ten parts, one of which is used for testing and the remaining nine parts is for training. We thus record average results to evaluate the performance. However, for the two large size samples: SUSY and HIGGS, the last 500,000 samples are used for testing, and the rest are for training. In our experiments, all features in each data set are scaled to $[-1, 1]$.

Example 5.4 (Real data with outliers). We still use these 13 real data sets in Example 5.3 but with adding outliers.

</tbody>
</table>

For each data set, we randomly pick $r$ percentage of training samples and then flip their labels. Same procedure is also applied into testing samples.

(f) Real data without outliers. Average results of five methods are recorded in Table 4. Note that some large size data sets make the other four methods run too much time, (e.g. over than one hour), so we do not report theirs results to relating those data sets. Clearly, $L_{0/1}$ADMM outperformed others in terms of biggest ACC, smallest NSV and shortest CPU for the most of data sets. More detailed, $L_{0/1}$ADMM and PSVM got better ACC than the other three methods. For instance, they predicted almost 90% samples correctly for col testing data whilst H SVM and PSVM only got less than 80% correct predictions. In terms of using support vectors, SSVM and PSVM again took all samples into consideration. By contrast, $L_{0/1}$ADMM made use of a few number of support vectors, e.g. 113 vs. 1247 by PSVM for adu data. As what we expected, $L_{0/1}$ADMM ran much faster than other methods for large size data sets because of small number of support vectors being used. For instance, 0.573 seconds vs. 36.95 seconds by H SVM for ijc data. In addition, it only took 14.26 seconds to get the solution for hig data with more than ten million samples. This demonstrated that $L_{0/1}$ADMM is capable of dealing with data in extremely large scales.

(g) Real data with outliers. We would like to see the performance of each method on solving the real date sets with outliers, namely Example 5.4. We choose different ratios $r$ from $\{0.01, 0.02, \ldots, 0.1\}$. As reported in Table 4, the other four methods suffered from the computational slowness for data sets with large sizes, thus we only present results of six data sets with small sizes: col, aus, two, mus, lek and spl. In terms of the accuracy in Figure 4, ACC obtained by all methods dropped down with $r$ ascending, namely, more outliers being added. Generally speaking, $L_{0/1}$ADMM got the highest ACC except for spl, followed by RSVM. As for NSV in Figure 5, SSVM and PSVM always took all samples. It can be seen that lines from $L_{0/1}$ADMM and RSVM did not go up when $r$ rose, which means they were quite robust to $r$, namely robust to the outliers. By contrast, more support vectors were needed by RSVM due to the rising of NSV when $r$ got increased. For each data set and each $r$, $L_{0/1}$ADMM always used the fewest support vectors, followed by RSVM and HSVM. When it comes to the CPU time in Figure 6, since col and lek have very small sizes, all methods got solutions quickly. While for other four data sets with moderate sizes, $L_{0/1}$ADMM ran fastest, and PSVM and RSVM came the last, such as, less than 0.1 second by $L_{0/1}$ADMM v.s. more than 100 seconds by PSVM and RSVM.

6 CONCLUSION

In this paper, we proposed a new soft-margin SVM model with the $L_{0/1}$ soft-margin loss function. It well captures the nature of the binary classification. The establishment of its optimality conditions made this NP-hard problem tractable. We then took advantage of the negative semidefinite proximal ADMM to solve this problem. The creation of $L_{0/1}$ support vectors greatly reduced the computational complexity. Extensive numerical experiments demonstrated that our proposed method enjoys high order of accuracy and super fast computational speed. What is more, since it only took very small number of support vectors into consideration, the proposed method turns out to be very robust to the outliers. The idea of using $L_{0/1}$ soft-margin loss function might be able to extend to deal with the different types of SVM models, such as SVM [38]–[41], which severely suffers from outliers. It is also interesting to see how similar method and techniques can be designed to solve the kernel SVM problems. We leave this topic as a future research.

APPENDIX A

PROOFS OF ALL THEOREMS

A.1 Proof of Lemma 2.1

Denote $\Omega(u) := \{i \in N_m : u_i = 0\}$ and $\Psi(u) := \{z \in \mathbb{R}^m : z_i \leq 0, \forall i \in \Omega(u)\}$. We split the proof of the lemma into the following two case:

Case 1: $u = 0$. For any $z \in \mathbb{R}^m$, it holds that $\|z_+\|_0 - \|u_+\|_0 - \langle v, z - u \rangle = -\langle v, z - u \rangle \geq 0 \forall z \in \Psi(u)$ and $z$ sufficiently closed to $u$. From the definition of the regular, limiting and horizon subdifferentials, we have

$$\widehat{\partial}\|u\|_0 = \partial\|u\|_0 = \partial^\infty\|u\|_0 = \mathbb{R}_+^m.$$

Case 2: $u \neq 0$. Since $\|u_+\|_0$ is lower-semicontinuous at $u$, there is a neighborhood $U(u, \delta)$ of $u$ such that $\|u_+\|_0 \leq \|z_+\|_0$ for all $z \in U(u, \delta)$ with $\delta > 0$. By the definition of the regular subdifferential of $\|u_+\|_0$, we only need to consider some sequence $z_j \in U(u, \delta) \cap \Psi(u)$ such that $z_j \to u$ and $\|z_j\|_+ = \|u\|_0$. For all such sequence $\{z_j\}$, we have

$$\|z_j\|_0 - \|u_+\|_0 - \langle v, z_j - u \rangle = -\langle v, z_j - u \rangle \geq 0$$

if and only if $v \in \Omega(u)$. Hence, $\widehat{\partial}\|u\|_0 = v \in \Omega(u)$. From the definition of the limiting subdifferential, letting $f := \|\cdot\|_0$, we have

$$\partial\|u\|_0 = \lim\sup_{z \rightarrow u} \langle u_+, v \rangle = \lim\sup_{v \in \mathbb{R}^m : v \in \Omega(u)} = \Omega(u).$$

Fig. 4: ACC v.s. r of five methods for solving six data sets.

Similarly, the horizon subdifferential of $\|u_+\|_0$ is given as the following,

$$
\partial^\infty \|u_+\|_0 = \lim_{\sigma \to 0} \sup_{\sigma \in ]0, \infty[} \sigma \partial \|z_+\|_0
= \lim_{\sigma \to 0} \sup_{\sigma \in ]0, \infty[} \{ \sigma v \in \mathbb{R}^m : v \in \Omega(z) \}
= \lim_{\sigma \to 0} \sup_{\sigma \in ]0, \infty[} \{ \sigma v \in \mathbb{R}^m : \sigma v \in \Omega(z) \}
= \lim_{\sigma \to 0} \{ v \in \mathbb{R}^m : v \in \Omega(z) \} = \Omega(u),
$$

where the third equation is due to $v \in \Omega(z)$ being equivalent to $\sigma v \in \Omega(z)$ for any $\sigma > 0$.

A.2 Proof of Lemma 2.2

It follows from (6) that

$$
\text{Prox}_{\alpha \ell_0/1} (s) = \arg \min_{u \in \mathbb{R}} \alpha \ell_0/1(u) + (u - s)^2/2.
$$

Let $\phi(u) := \alpha \ell_0/1(u) + (u - s)^2/2$. Since $\phi_1(u) := \alpha + (u - s)^2/2$ for $u > 0$ and $\phi_2(u) := (u - s)^2/2$ for $u < 0$ are strongly convex and twice continuously differentiable, the unique minimal values of $\phi_1(u)$ and $\phi_2(u)$ are both attained at $u = s$. Moreover, $\phi_3(u) := (u - s)^2/2$ for $u = 0$, we have $\phi_3(0) = s^2/2$. The rest part is to compare the three values $\phi_1(s)$ with $s > 0$, $\phi_2(s)$ with $s < 0$ and $\phi_3(0)$: (i) Since $s > \sqrt{2/\alpha} \Leftrightarrow \phi_3(0) > \phi_1(s)$ and $\phi_2(s) > \phi_1(s)$, we can observe that the minimal value of $\phi(u)$ is achieved at $u = s$. (ii) Since $0 \leq s < \sqrt{2/\alpha} \Leftrightarrow \phi_1(s) > \phi_3(0)$ and
\( \phi_2(s) > \phi_3(0) \), similarly, we have \( u = 0 \). (iii) Since \( s < 0 \Leftrightarrow \phi_1(s) > \phi_2(s) \) and \( \phi_3(0) > \phi_2(s) \), it is easy to see that \( u = s \).

(iv) Since \( s = \sqrt{2t} \Leftrightarrow \phi_2(s) > \phi_1(s) = \phi_3(0) \), then \( u = 0 \) or \( s \). Thus, we have (7), which completes the proof. \( \square \)

### A.3 Proof of Lemma 2.4

(i) It follows from (11) that

\[
 f_\gamma(u, z) = C\|u_+\|_0 + h(z) + \langle \nabla h(z), u - z \rangle + \frac{1}{2\gamma}\|u - z\|^2
\]

\[
= C\|u_+\|_0 + h(z) - \frac{1}{2\gamma}\|\nabla h(z)\|^2
\]

\[
+ \frac{1}{2\gamma}(\|u - z\|^2 + 2\gamma\langle \nabla h(z), u - z \rangle + \|\nabla h(z)\|^2)
\]

\[
= C\|u_+\|_0 + \frac{1}{2\gamma}\|u - (z - \nabla h(z))\|^2
\]

+ (constant term independent of \( u \)).

Hence, the global solution of problem (11) for any fixed \( \gamma, C > 0 \) and \( z \in \mathbb{R}^m \) is equivalent to

\[
 u^* = \arg\min_{u \in \mathbb{R}^m} C\|u_+\|_0 + \frac{1}{2\gamma}\|u - (z - \nabla h(z))\|^2
\]

\[
= \text{prox}_{\gamma C L_0/1}(z - \gamma \nabla h(z)).
\]

(ii) Since \( h \) is gradient Lipschitz continuous with a Lipschitz constant \( \nu_h > 0 \), then for any \( 0 < \gamma \leq 1/\nu_h \), we have

\[
h(u) \leq h(u^*) + \langle \nabla h(u^*), u - u^* \rangle + \frac{\nu_h}{2}\|u - u^*\|
\]

from [27, Lemma 2.3]. This together with (11) yields that

\[
f_\gamma(u, u^*)
\]

\[
= C\|u_+\|_0 + h(u^*) + \langle \nabla h(u^*), u - u^* \rangle + \frac{1}{2\gamma}\|u - u^*\|^2
\]

\[
\geq C\|u_+\|_0 + h(u^*) + \langle \nabla h(u^*), u - u^* \rangle + \frac{\nu_h}{2}\|u - u^*\|^2
\]

\[
\geq C\|u_+\|_0 + h(u) \geq C\|u_+\|_0 + h(u^*) = f_\gamma(u^*, u^*)
\]

the last inequality is from the global optimality of \( u^* \), which completes the proof. \( \square \)

### A.4 Proof of Theorem 3.1

From (4), one can easily check that

\[
\min_{w \in \mathbb{R}^n, b \in \mathbb{R}} f(w; b) \leq f(1; b) < n^2 + Cm < +\infty.
\]

Next we prove the level set \( S := \{(w; b) \in \mathbb{R}^{n+1} : f(w; b) < n^2 + Cm\} \) is non-empty and bounded. Clearly, \( S \neq \emptyset \) due to \((1; b) \in S \). Since \( b \) is finite-valued, we can obtain that \( b \) is bounded. Moreover, \( Cm + n^2 > f(w; b) \geq \|w\|^2/2 \), which indicates \( w \) is bounded. Hence, the level set \( S \) of \( f \) is non-empty and bounded and a global minimizer exists. \( \square \)

### A.5 Proof of Theorem 3.2

(Necessity) Suppose that \( \phi^* := (w^*; b^*; u^*) \in \Theta \) is a local minimizer of problem (13), where \( \Theta \) is the feasible set in
Then we have the following chain of relations

\[ 0 \leq \partial\left(\|\mathbf{w}^*\|^2/2 + \delta_\Theta(\phi^*) + C\|\mathbf{u}_+\|_0\right) \]
\[ \leq \partial\|\mathbf{w}^*\|^2/2 + \delta_\Theta(\phi^*) + \partial C\|\mathbf{u}_+\|_0 \]
\[ \leq \partial\|\mathbf{w}^*\|^2/2 + \delta_\Theta(\phi^*) + \partial C\|\mathbf{u}_+\|_0 \]
\[ = (\mathbf{w}^*; 0; 0) + N_\Theta(\phi^*) + C(0; 0; 0; \partial\|\mathbf{u}_+\|_0) \]
\[ = (\mathbf{w}^*; 0; 0) + \text{Im}(A^\top; \text{Diag}(\mathbf{y}); I) + C(0; 0; 0; \partial\|\mathbf{u}_+\|_0) \]
\[ = (\mathbf{w}^* + A^\top \lambda^*; \mathbf{y}^* I; \lambda^*; C\partial\|\mathbf{u}_+\|_0 + \lambda^*) \]

where (a), (b), (d) and (e) hold from [17, Theorem 10.1], [24, Corollary 10.9], [23, Example 2.32] and [23, Proposition 2.12] respectively. (c) is due to the convexity of \|\mathbf{w}^*\|^2/2 and \delta_\Theta(\phi^*) and Lemma 2.1. Here, \delta_\Theta(z) is the indicator function, namely, \delta_\Theta(z) = 0 if z \in \Theta and \delta_\Theta(z) = +\infty otherwise. \text{N}_\Theta(z) is the normal cone of the convex set \Theta at point z, which is defined as \text{N}_\Theta(z) = \{v : \langle v, z - x \rangle \geq 0, \forall x \in \Theta\}. \text{Im}(B) is the image of matrix B, i.e., \text{Im}(B) := \{\lambda x : \lambda \in \mathbb{R}^m\}, I is the identity matrix. Finally, (w^*, b^*, u^*) \in \Theta implies u^* - 1 + Aw^* + b^* y = 0.

(Sufficiency) Suppose \phi^* = (w^*, b^*, u^*) and \lambda^* \in \mathbb{R}^m satisfy (15). For a given C > 0, (15) suffices to

\[ 0 \in \left\{ \begin{bmatrix} \mathbf{w}^* + A^\top \lambda^* \\ (\mathbf{y}^*, \lambda^*) \\ C\partial\|\mathbf{u}_+\|_0 + \lambda^* \end{bmatrix} \right\}. \]

Denote \text{I}(\mathbf{u}^*) := \{i \in \mathbb{N}_m : u^*_i = 0\} and consider a problem

\[ \min_{\mathbf{u} \in \mathbb{R}^n, b \in \mathbb{R}, \mathbf{w} \in \mathbb{R}^m} \frac{1}{2}\|\mathbf{w}\|^2 \\
\text{s.t.} \quad \mathbf{u} = 1 - (Aw + by), \quad u_i \leq 0, \quad i \in \text{I}(\mathbf{u}^*), \]

which is convex and thus has a global optimal solution (w^*, b^*, u^*). It satisfies that there exists (\lambda, \mu) such that

\[ \begin{align*}
\mathbf{w} + A^\top \lambda &= 0, \\
\langle \mathbf{y}, \lambda \rangle &= 0, \\
Aw + \mathbf{b}y + \mathbf{u} - 1 &= 0 \quad \text{(37)}
\end{align*} \]

By the expression of \partial\|\mathbf{u}_+\|_0 in (5), (34) and \(Aw^* + b^* y + u^* - 1 = 0\) means (\phi^*, \lambda^*) satisfy (37), which indicates \phi^* is a global solution of problem (35). Therefore, we have

\[ \frac{1}{2}\|\mathbf{w}^*\|^2 \leq \frac{1}{2}\|\mathbf{w}\|^2, \quad \forall (\mathbf{w}; b; \mathbf{u}) \in \Theta_1, \]

where \Theta_1 is the feasible set of (35).

The function C\|\mathbf{u}_+\|_0 is lower semi-continuous at \phi^* \in \Theta, then by [23, Proposition 4.3], there is a neighborhood \(U(\phi^*, \delta_1)\) of \phi^* with \delta_1 > 0 such that

\[ \|\mathbf{u}_+\|_0 \geq \|\mathbf{u}_+\|_0 - \frac{1}{2}, \forall (\mathbf{w}; b; \mathbf{u}) \in \Theta \cap U(\phi^*, \delta_1). \]

While \|\mathbf{u}_+\|_0 can only take values from \{0, 1, \cdots, m\}. It allows us to conclude that

\[ \|\mathbf{u}_+\|_0 \geq \|\mathbf{u}_+\|_0, \forall (\mathbf{w}; b; \mathbf{u}) \in \Theta \cap U(\phi^*, \delta_1). \]

Clearly, \Theta_1 \subseteq \Theta. If any (w; b; u) \in \Theta \cap U(\phi^*, \delta_1), then (37) and (38) lead to

\[ \frac{1}{2}\|\mathbf{w}^*\|^2 + C\|\mathbf{u}_+\|_0 \leq \frac{1}{2}\|\mathbf{w}\|^2 + C\|\mathbf{u}_+\|_0. \]
If any \((w; b; u) \in ((\Theta \setminus \Theta_1)) \cap U(\phi^*, \delta_1)\), then there exists \(i_0 \in \mathbb{I}(u^*)\) with \(u_{i_0}^* = 0\) but \(u_{i_0} > 0\), which implies \(\|(u_{i_0}^*)_+\|_0 = 0\) but \(\|(u_{i_0})_+\|_0 = 1\). By (38), we have
\[
\|u_+\|_0 \geq \|u^*_+\|_0 + 1. \tag{40}
\]
Since \(\|w\|^2/2\) is locally lipschitz continuous in \(\mathbb{R}^n\), there exists a neighborhood \(U(\phi^*, \delta_2)\) of \(\phi^*\) with \(\delta_2 > 0\) such that
\[
\|w\|^2 - \|w^*\|^2 \leq 2C, \quad \forall (w; b; u) \in U(\phi^*, \delta_2). \tag{41}
\]
Taking \(\delta = \min(\delta_1, \delta_2)\), and combining (40) and (41), we obtain for any \((w; b; u) \in (\Theta \setminus \Theta_1) \cap U(\phi^*, \delta_2)\)
\[
\frac{1}{2} \|w^*\|^2 + C\|u^*_+\|_0 \leq \frac{1}{2} \|w^*\|^2 + C\|u_+\|_0 - C
\]
\[
\leq \frac{1}{2} \|w\|^2 + C\|u_+\|_0. \tag{42}
\]
Overall, we prove the global optimality of \(\phi^*\) in a local region \(\Theta \cap U(\phi^*, \delta)\).
\[
\Box
\]
\[ \text{A.6 Proof of Theorem 3.3} \]
Denote \(g(u) \equiv \|H(u - 1)\|^2/2\) in (17) with gradient \(\nabla g(u) = H^\top H(u - 1)\). From Theorem 2.1, we have
\[
u^* = \text{prox}_{\gamma, \mathbb{C}L_{0/1}}(u^* - \gamma \nabla g(u^*)), \tag{43}
\]
for any \(0 < \gamma \leq \gamma_H\). Because \(B\) has a full column rank, \(B^+\) exists, namely, \(B^+ = (B^\top B)^{-1}B^\top\). Now, let \(\lambda^* = \nabla g(u^*)\). Then we have
\[
-\lambda^* = H^\top H(u^* - 1) = H^\top EB^+(u^* - 1) = H^\top E \begin{bmatrix} w^* \\ b^* \end{bmatrix},
\]
where \(E := \begin{bmatrix} I_{n \times n} & 0 \\ 0 & 0 \end{bmatrix},\) which suffices to
\[
-B^\top \lambda^* = B^\top H^\top E \begin{bmatrix} w^* \\ b^* \end{bmatrix} = B^\top (B^+)^\top E^\top E \begin{bmatrix} w^* \\ b^* \end{bmatrix} = \begin{bmatrix} w^* \\ 0 \end{bmatrix}. \tag{44}
\]
By the definition of \(B := [A \ y]\), above equation yields
\[
\begin{cases}
w^* + A^\top \lambda^* = 0, \\
(y, \lambda^*) = 0.
\end{cases}
\]
Finally, the above conditions, the feasibility of \((w^*; b^*; u^*)\) and (43) lead to (18).
\[
\Box
\]
\[ \text{A.7 Proof of Theorem 3.4} \]
According to (15) and (18), we only need to show that if \((u^*; \lambda^*)\) satisfies \(u^* = \text{prox}_{\gamma, \mathbb{C}L_{0/1}}(u^* - \gamma \lambda^*)\) in (18) with \(C > 0\) and \(0 < \gamma \leq \gamma_H\), then \(0 \in C\partial \|u^*_+\|_0 + \lambda^*\) in (15). In fact, it follows from (8) and (9) that for any \(i \in \mathbb{N}_m\),
\[
u_i^* = \begin{cases} 0, & 0 \leq v_i \leq \sqrt{2C}/\gamma \\ v_i, & \text{otherwise} \end{cases}
\]
where \(v := u^* - \gamma \lambda^*\). This means for any \(i\) with \(u_i^* = 0\), \(-\sqrt{2C}/\gamma \leq \lambda_i^* \leq 0\) and for any \(i\) with \(u_i^* = v_i = u_i^* - \gamma \lambda_i^*, \lambda_i^* = 0\). Finally, the expression of \(\partial \|u^*_+\|_0\) in Lemma 2.1 allows us to complete the proof immediately.
\[
\Box
\]
\[ \text{A.8 Proof of Theorem 4.1} \]
Since \(T_k \subseteq \mathbb{N}_m\) has finite many elements, for sufficient large \(k\), there is a subset \(J \subseteq \{1, 2, 3, \ldots\} \) such that
\[
T_j \equiv T, \quad \forall j \in J. \tag{44}
\]
For notational simplicity, denote \(\phi^k := (w^k, b^k, u^k, \lambda^k)\) and \(\phi^* := (w^*, b^*, u^*, \lambda^*)\). As \(\{\phi^j\} \to \phi^*\), it follows \(\{\phi^j\} \to \phi^*\). Taking the limit along with \(J\) of (33), namely, \(k \in J, k \to \infty\), we have
\[
\left\{ \begin{array}{l} 
\lambda_j^* = \lambda^* + \eta \sigma w_j^* \\
\lambda_j^* = 0,
\end{array} \right. \tag{45}
\]
which derives \(w_j^* = 0\). Taking the limit along with \(J\) of (23) and (44) respectively yields
\[
\begin{aligned}
z^* &= 1 - Aw^* - b^* y - \lambda^* / \sigma \\
&= 1 - Aw^* - b^* y - u^* - \lambda^* / \sigma \\
&= -w^* + u^* - \lambda^* / \sigma, \tag{46}
\end{aligned}
\]
and thus
\[
\begin{aligned}
u_T^* &= 0, \quad u_T^* = z_T^* = -w_T^* + u_T^* - \lambda_T^* / \sigma \tag{47} \\
&= -w_T^* + u_T^*,
\end{aligned}
\]
This proves \(w_T^* = 0\) and hence \(w^* = 0\). Again by (46), we obtain \(z^* = u^* - \lambda^*/\sigma\), which together with (47) and the definition of proximal operator (9) indicates
\[
u^* = \text{prox}_{\gamma, \mathbb{C}L_{0/1}}(z^*) = \text{prox}_{\gamma, \mathbb{C}L_{0/1}}(u^* - \lambda^*/\sigma). \tag{48}
\]
Now taking the limit along with \(J\) of (28) results in
\[
(I + \sigma A_T^\top A_T)w^* = \sigma A_T^\top v_T^* = -\sigma A_T^\top (u_T^* + b^* y_T - 1 + \lambda_T^* / \sigma) = -\sigma A_T^\top (w_T^* - A_T w^* + \lambda_T^*/\sigma) = -\sigma A_T^\top (A_T w^* + \lambda_T^*/\sigma),
\]
where \(v^* = -(u^* + b^* y - 1 + \lambda^*/\sigma)\) and the last two equations hold due to \(w_T^* = u^* + Aw^* + b^* y - 1 = 0\). The last equation suffices to that
\[
w^* = -A_T^\top \lambda_T^* \tag{45},
\]
Finally taking the limit along with \(J\) of (32) leads to
\[
\begin{aligned}
b^* &= \langle y, r^* \rangle / m = -\langle y, Aw^* - 1 + u^* + \lambda^*/\sigma \rangle / m \\
&= -\langle y, b^* y + \lambda^*/\sigma \rangle / m
&= b^* - \langle y, \lambda^*/m \sigma \rangle,
\end{aligned}
\]
which contributes to \(\langle y, \lambda^* \rangle = 0\). Overall, we have
\[
\begin{aligned}
w^* + A^\top \lambda^* &= 0, \\
(y, \lambda^*) &= 0, \\
u^* + Aw^* + b^* y &= 1, \\
\text{prox}_{\gamma g, \mathbb{C}L_{0/1}}(u^* - \lambda^*/\sigma) &= u^*.
\end{aligned}
\]
Namely, \((w^*; b^*; u^*)\) is a P-stationary point of problem (13) where \(\gamma = 1/\sigma\).
