On the Channel Capacity of Layered ACO-OFDM

Xiaoyu Zhang, Student Member, IEEE, Sheng Chen, Fellow, IEEE, and Lajos Hanzo, Fellow, IEEE

Abstract—Layered Asymmetrically Clipped Optical Orthogonal Frequency Division Multiplexing (LACO-OFDM) has been proposed for optical communications and has attracted much attention, thanks to its flexibility in terms of power vs. spectral efficiency. In this paper, we propose algorithms for optimizing the Discrete-input Continuous-output Memoryless Channel (DCMC) capacity of LACO-OFDM. Then, an algorithm is proposed for maximizing the capacity for twin-layer LACO-OFDM by optimizing the power sharing between the layers. This is followed by the conception of a more general algorithm applicable to LACO-OFDM having an arbitrary number of layers. Numerical results are provided for quantifying the capacity improvement attained by the proposed algorithm. Moreover, an adaptive scheme is proposed for adjusting the number of layers to be used for maximizing the capacity at different SNRs.

Index Terms—LACO-OFDM, capacity, optimization, power sharing, adaptive

I. INTRODUCTION

Optical Wireless Communication (OWC) is expected to play a role as a potential component of next generation wireless systems, as a benefit of its low delay and low power consumption, as well as high integrity [1], [2]. Apart from these benefits, the substantial unlicensed visible light band spanning roughly from 400 to 800 THz band can be readily exploited by low-cost off-the-shelf transmitters, such as Light-Emitting Diodes (LEDs) [3]. Intensity Modulation combined with Direct Detection (IM/DD) has attracted much attention as a benefit of its low-cost components [4]. Following Armstrong's seminal contribution, the popularity of Orthogonal Frequency Division Multiplexing (OFDM) has grown in OWC, since its design has been well understood in the Radio Frequency (RF) industry [5], [6], [7]. While RF-OFDM produces complexvalued signals, the IM/DD can only handle pure real and nonnegative values, which has led to several proposals for OWCspecific OFDM (O-OFDM) schemes [7].

Historically, Carruthers and Kahn proposed Direct Current (DC) biased Optical OFDM (DCO-OFDM) [8] by exploiting that an Hermitian-symmetric Frequency Domain (FD) OFDM symbol has a real-valued Time Domain (TD) representation after Inverse Fast Fourier Transform (IFFT) based modulation [5]. Then, the resultant TD signal having negative and positive values is offset by a sufficiently high DC voltage for ensuring that the resultant signal only has negligible negative samples. These small negative samples are then clipped before intensity modulation. In 2006, the Asymmetrically Clipped

Optical OFDM (ACO-OFDM) philosophy was proposed by Armstrong and Lowery for mitigating the high power consumption of the DC-offset and for reducing the clippinginduced distortion in DCO-OFDM [9]. In addition to the 50% throughput loss imposed by the Hermitian symmetry requirement, the ACO-OFDM scheme leaves every other subcarriers blank in the FD for ensuring that clipping the negative contributions results in FD distortions falling onto the blank subcarriers. As an explicit benefit, the subcarriers loaded with information symbols are then free from distortion and in this way no information contamination occurs, but unfortunately this further halves the throughput. More explicitly, while ACO-OFDM avoids the high power consumption of DCO-OFDM, hence requiring a lower SNR, this is facilitated by transmitting only half the information within the same bandwidth [10]. This then leads to a power- vs. spectral- efficiency tradeoff, when deciding which scheme to utilize. But naturally, the power saved by using blank subcarriers may be invested into the active subcarriers either for reducing their BER or for enhancing their throughput [11], [12].

Hence, several solutions have been conceived for striking a compromise between the power consumption and bandwidth efficiency [13], [14], [15], [16]. Layered ACO-OFDM (LACO-OFDM) proposed by Wang et al. [15] is one of the recent breakthroughs. But a variety of other schemes like the Spectral and Energy Efficient OFDM (SEE-OFDM) scheme of [17], [18] and the enhanced ACO-OFDM arrangement (eACO-OFDM [19] and EACO-OFDM [20]) have also relied on a similar philosophy. In simple tangible terms, LACO-OFDM strategically exploits the subcarriers left blank by ACO-OFDM and loads an additional ACO-OFDM signal onto them. The additional signal, termed as the second layer, has half the bandwidth of the original ACO-OFDM (referred to as the first layer), thus improving the overall bandwidth efficiency by 50%. After the superposition of the two layers, the resultant signal is known as a 2-layer (or twin-layer) LACO-OFDM signal. This operation can be repeated by exploiting the remaining blank subcarriers, loading the third, fourth and other layers. Naturally, transmitting more layers increases the overall power consumption. Therefore, LACO-OFDM beneficially improves the spectral efficiency of ACO-OFDM at the cost of reducing its power efficiency [21], [22], [23], striking a flexible tradeoff.

Recent studies of the LACO-OFDM capacity [24], [25], [26] have been focused on the Continuous-input Continuous-output Memoryless Channel (CCMC) capacity, which is unbounded and as dictated by Shannon's ubiquitous capacity formula [27], subject to the unipolar IM/DD constraint. To expound a little further, Li *et al.* [24] studied the CCMC capacity of ACO-OFDM under both AWGN and fading channels. The CCMC capacity of LACO-OFDM was derived in [25] by

Zhou and Zhang, who also compared it with other O-OFDM schemes. On the other hand, the Discrete-input Continuousoutput Memoryless Channel (DCMC) capacity of LACO-OFDM requires more attention. Naturally, the DCMC capacity is a more realistic bound, since practical discrete modulation schemes are considered. It was revealed in [28] that modulation schemes whose modulation-order is excessively high may not be suitable for O-OFDM, given their vulnerability to clipping distortion.

Against this background, we focus our attention on maximizing the total DCMC capacity of a LACO-OFDM system. Explicitly, our contributions may be summarized as follows:

- We derive the DCMC capacity of a LACO-OFDM system as a function of the Signal-to-Noise Ratio (SNR) and the number of layers in the system, as well as the power sharing amongst the layers. In this paper, the DCMC capacity is hereafter referred to as "channel capacity" or simply "capacity".
- We provide an algorithm for determining the optimum power-sharing strategy for twin-layer LACO-OFDM at a given SNR, followed by our generalized algorithm.
- Finally, we compare the optimized capacities of LACO-OFDM systems relying on different number of layers, which leads to an adaptive scheme using the optimum number of layers for maximizing the capacity at a given SNR.

A. Paper Structure

This paper is organized as follows. In Sec. II, the architecture of the LACO-OFDM transceiver is discussed, followed by our DCMC capacity expression derived in Sec. III. Section IV focuses on the optimization of a twin-layer LACO-OFDM system's capacity, which is then extended to a system having three or more layers in Sec. V. The algorithm proposed is further evaluated in Sec. VI. Finally, Sec. VII concludes this paper.

B. Nomenclature

We use C, P and Γ to represent the capacity, power and SNR, respectively, as defined formally in due course. Their subscript represents a standalone layer of the LACO-OFDM scheme, while "RF", "ACO" and "LACO" refer to the overall multi-layer scheme. For example, $P_{\rm LACO}$ represents the total power of the LACO-OFDM system, while P_2 represents the power of the 2nd layer in a LACO-OFDM system.

Furthermore, $\frac{\partial f}{\partial x}$ is the partial derivative of the function f with respect to x, while $\frac{\partial f}{\partial x}\Big|_{x_0}$, $\frac{\partial f}{\partial x}\Big|_{g(x_0)}$ is the value of the derivative at the points of $x = x_0$ and $x = g(x_0)$, respectively. In addition, $\frac{\partial h}{\partial x}\Big|_{(x_0,y_0)}$ evaluates the partial derivative of h with respect to x at the point (x_0, y_0) .

II. SYSTEM MODEL

We commence by introducing the basic structure of an ACO-OFDM system, before expounding further on more sophisticated LACO-OFDM systems. The multi-class coded LACO-OFDM of [22] is employed for exploiting its low interlayer interference (ILI).

Fig. 1. Schematic of an ACO-OFDM transmitter.

A. ACO-OFDM

Figure 1 shows the schematic of an ACO-OFDM system, where the shaded area at the top represents the transmitter (ACO-TX), and the one at the bottom the receiver (ACO-RX).

The input bit stream **b** of the ACO-TX is firstly mapped¹ to the discrete symbols of a given Quadrature Amplitude Modulation (QAM) or Phase Shift Keying (PSK) constellation pattern. The symbols $S = \{S[0], S[1], \ldots, S[k], \ldots\}$ are then loaded¹ to the stream \overline{S} under the ACO-OFDM loading rule of (1), where the ACO-OFDM scheme is capable of conveying K/4 symbols mapped to K subcarriers, with $S^*[k]$ being the conjugate of symbol S[k].

$$\bar{S}[u] = \begin{cases} S[k], & u = 2k + 1, \\ S^*[k], & u = K - (2k + 1), \\ 0, & \text{otherwise.} \end{cases} \quad \begin{array}{l} 0 \le u \le \frac{K}{4}, \\ 0 \le k \le K, \end{array}$$
(1)

The resultant signal is processed by a *K*-point IFFT, which transforms it to its TD counterpart $\bar{s} = \{\bar{s}[0], \bar{s}[1], \ldots\}$. The mapping rule (1) enforces the Hermitian symmetry in \bar{S} , which ensures that the TD signal \bar{s} is purely real-valued. Moreover, (1) maps a null symbol to every other subcarrier, which results in further symmetry formulated \bar{s} as

$$\bar{s}[k] = -\bar{s}[K-k]. \tag{2}$$

Hence, despite clipping all negative samples in \bar{s} , all the information can be losslessly recovered from the resultant signal s. The clipped signal s^c is unipolar, thus it can be forwarded to the optical front end of Fig. 1.

The received signal of Fig. 1 is then converted back to the electric TD by the direct detection block of Fig. 1, yielding the signal r, before passing it to the ACO-RX block. The unipolar signal r is firstly transformed back to the FD signal \overline{R} of length K by the K-point FFT. Again, the "lossless clipping" operation imposed by the ACO-TX block of Fig. 1 actually results in clipping distortions that are accommodated by the even-indexed subcarriers, *i.e.* those marked in (1) as "otherwise". Therefore, the desired symbols can be readily

¹To avoid confusion, in this paper, we refer to bit-to-symbol "mapping" when we discuss the action of the "Mapping" block of Fig. 1 generating the stream S from b. By contrast, the action of the "Loading" block of Fig. 1 is termed as "loading", which creates the symbol stream \bar{S} from S, according to the ACO-OFDM rules.

Fig. 2. Schematic diagram of a multi-class coded LACO-OFDM transmitter, where each "ACO-TX" block is similar, but not identical to the architecture of Fig. 1.

extracted from the first K/4 odd-indexed subcarriers of \bar{R} $(\bar{R}[1], \bar{R}[3], \ldots, \bar{R}[K/2 - 1])$ to form R of Fig. 1. Following symbol-to-bit constellation demapping, the receiver obtains the information bits \hat{b} .

B. Multi-Class Coded LACO-OFDM Transmitter

Figure 2 shows the detailed layer-based schematic of a multi-class channel-coded LACO-OFDM transmitter.

In LACO-OFDM, the original bit stream is split into L layers as $\{b_1, \ldots, b_L\}$. Forward Error Correction (FEC) channel encoders are employed for each individual layer's bit streams, producing the channel-encoded stream $\{\tilde{b}_1, \ldots, \tilde{b}_L\}$, each having its own ACO-TX block similar to, but not identical to, that of Fig. 1. Explicitly, the following modifications have to be carried out for ensuring that the symbols mapped to higher layers (*i.e.* those having a higher layer index l) always fall on the subcarriers left blank by the lower layers. Explicitly, the loading rule for the lth layer is now:

$$\bar{S}_{l}[u] = \begin{cases} S_{l}[k], & u = 2^{l}k + 2^{l-1}, \\ S_{l}^{*}[k], & u = K - (2^{l}k + 2^{l-1}), \\ 0, & \text{otherwise}, \end{cases}$$
(3)
$$1 \le l \le L, \ 0 \le u \le \frac{K}{2^{l+1}} \text{ for } S_{l}[k], \ 0 \le k \le K, \end{cases}$$

where $S_l[k]$ is the kth symbol for the lth layer.

Hence, the *l*th layer is capable of accommodating $K/2^{l+1}$ symbols, *i.e.* the signal \bar{S}_l should have $K/2^{l+1}$ non-zero subcarriers. Therefore, LACO-OFDM having *L* layers is capable of conveying a total of $[(K/2) \times (1 - 1/2^L)]$ symbols, nearly doubling the normalized throughput of the ACO-OFDM scheme. The signals loaded onto each layer of Fig. 2 are then independently subjected to *K*-point IFFT, whose output should obey (2), which can have all its negative samples clipped in order to form the unipolar signals s_l .

Observe in Fig. 2 that a power control module is employed after clipping for ensuring that each layer has the most appropriate power share. A set of power sharing factors $\alpha = \{\alpha_1, \alpha_2, \dots, \alpha_{L-1}\}$ is used by these power controllers for ensuring that the signal s_l has an electric power of P_l . This process will be further discussed in Secs. IV and V.

Finally, the signals having the optimal power are superimposed for constructing the TD signal s_{LACO} , which completes the LACO-OFDM transmitter's signal processing actions seen in Fig. 4.

Fig. 3. FD representation of a 3-layer LACO-OFDM signal having 16 subcarriers [21]. The "North-East" hatching, vertical hatching and "North-West" hatching represent the clipping distortions of the 1st, 2nd and 3rd layer, respectively.

C. Frequency Domain Representations of LACO-OFDM

To elaborate further on the operation of LACO-OFDM, the FD representation of a 3-layer LACO-OFDM signal is portrayed in Fig. 3.

According to (3), the symbols $S_1[0]$, $S_1[1]$, $S_1[2]$ and $S_1[3]$ assigned to the first layer occupy subcarriers 1, 3, 5, and 7, while their respective conjugates are loaded onto subcarriers 15, 13, 11 and 9. After clipping the negative part of the TD signal, the distortions generated will only contaminate the even-indexed subcarriers, *i.e.* k = 0, 2, ..., 14, thanks to the property of "lossless clipping" inherited from ACO-OFDM. The 1st layer's distortions are represented by the "North-East" hatching in Fig. 3.

Similarly, for the 2nd layer, the symbols are loaded onto the subcarriers at k = 2, 6, while their conjugates onto k = 14, 10 and their clipping distortions contaminate the subcarriers k = 0, 4, 8, 12 marked by vertical hatching. When k = 16, the 3rd layer may only have 1 symbol, which is located at subcarrier k = 4 and has its conjugate at subcarrier k = 12, while its clipping distortions are represented by the "North-West" hatching blocks at subcarriers k = 0 and k = 8.

Therefore, in LACO-OFDM, a subcarrier-symbol can only be placed together with distortions produced from its lower layers, but it remains orthogonal to all other subcarriersymbols of the same layer. Moreover, the symbols of the 1st layer are entirely free from clipping distortion, hence they can be directly detected without resorting to interferencecancellation. By contrast, the upper layers have to be decontaminated from the distortion products imposed by the lower layers. But fortunately, this can be readily achieved by an iterative clean-up operation commencing with the uncontaminated 1st layer.

D. Multi-Class Coded LACO-OFDM Receiver

Based on the discussions of Sec. II-C, let us now present the receiver design of multi-class coded LACO-OFDM, which is shown in Fig. 4.

Based on classic direct detection, the received optical signal is first converted into its electric domain representation by a photo detector, and then from the TD to its FD representation by the K_l -point FFT, like for the ACO-OFDM signal of Fig. 1. The subcarrier detection of a LACO-OFDM signal at the receiver commences from the uncontaminated first layer, whose symbols are completely free from the interference produced by the clipping distortion. Hence, they can be directly extracted. A soft-output QAM demapper is employed to calculate the *a*

Fig. 4. Schematic diagram of a multi-class coded LACO-OFDM receiver, where the "HD" blocks represent hard decision makers.

priori Log-Likelihood Ratio (LLR) of the encoded bits $\mathcal{L}_{a}(\boldsymbol{b}_{1})$ from the extracted symbol stream \hat{S}_1 . This information will be forwarded to a channel decoder having the corresponding FEC code paired with the FEC encoder of Fig. 2, which provides the a posteriori LLR of the uncoded bit stream $\mathcal{L}_{p}(\boldsymbol{b}_{1})$. Following hard-decision (HD), the detected bit stream b_1 of layer 1 is obtained. The soft-output demapper also generates the *a posteriori* LLR $\mathcal{L}_{p}(\tilde{b}_{1})$ of the coded bit stream for a better estimation of \hat{b}_1 , which will then be re-modulated to reconstruct the layer's unipolar signal \hat{s}_1 at the receiver by going through the entire modulation process of mapping, loading, IFFT, clipping and power sharing, as seen in Fig. 4. In this way, the TD-clipping-induced FD distortions caused by the 1st layer can be reproduced at the receiver, which can then be subtracted from the received signal. Viewing this process in Fig. 3, it wipes out all interference products at the "bottom level" of that tripple-level structure.

Still referring to Fig. 3, it becomes clear that the symbols on the 2nd layer are now free from the TD-clipping-induced FD interference as well. The detection process of the 1st layer can then be repeated for the 2nd layer, reproducing the locally reconstructed 2nd layer information bits and wiping out the interference, as seen in Fig. 4. This is followed by the same detection process for the 3rd layer, and if applicable to the 4th layer and so on.

Finally, the bits output by each layer are combined into a single bit stream and form the final output stream.

III. DCMC CAPACITY OF LACO-OFDM

A. DCMC Capacity of an RF-OFDM System

Let us define the channel SNR Γ as the channel energy per symbol (E_s) to noise power spectral density (N_0) ratio, namely as $\Gamma = E_s/N_0$ for an RF system. The channel capacity of an *M*-QAM scheme is [29], [30]

$$C_{\rm RF}(\Gamma) = (\text{Sink Entropy}) - (\text{Noise Entropy})$$
$$= \underbrace{-\int_{-\infty}^{\infty} p(R) \log_2\left[p(R)\right] \, \mathrm{d}R}_{(a)} - \underbrace{\log_2\left(\frac{\pi e}{\Gamma}\right)}_{(b)}, \quad (4)$$

where part (b) in (4) represents the entropy of the noise, which is complex-valued having a variance of N_0 . Furthermore, in part (a) of (4), the integration should take place across the entire complex-valued plane, if high order modulation (M > 2) is applied, where the probability p(R[n]) of the received symbols is given by

$$p(R[n]) = \frac{1}{M} \sum_{m=1}^{M} p(R[n]|\mathcal{S}^{(m)})$$

$$= \frac{1}{M} \sum_{m=1}^{M} \left[\frac{\Gamma}{\pi} \cdot \exp\left(-\Gamma \cdot \left| R[n] - \mathcal{S}^{(m)} \right|^2 \right) \right] \quad (5)$$

$$= \frac{\Gamma}{\pi M} \sum_{m=1}^{M} \exp\left(-\Gamma \cdot \left| R[n] - \mathcal{S}^{(m)} \right|^2 \right),$$

where $S^{(m)}$ is the *m*th points in the *M*QAM constellation *S* having a unity average power, and $p(r|S^{(m)})$ is the complexvalued Gaussian distribution PDF with a mean of $S^{(m)}$ and variance of $1/\Gamma$. This part cannot be analytically evaluated, due to the summation within the logarithm shown in (5). However, Monte-Carlo method can be used for approximating it by generating a sufficiently high number of received symbol realizations ($\mathbf{R} = R[1], R[2], \ldots, R[n], \ldots$), yielding

$$(a) = \mathbb{E}\left[-\log_2(p(R))\right] \approx -\frac{1}{N} \sum_{n=1}^N \log_2\left[p(R[n])\right], \quad (6)$$

where $\mathbb{E}[\cdot]$ is the statistical expectation, and the approximation converges as $N \to \infty$. Hence, (4) can be simplified as:

$$C_{\rm RF}(\Gamma) \approx -\log_2\left(\frac{\pi e}{\Gamma}\right) - \frac{1}{N} \sum_{n=1}^N \log_2\left[\frac{\Gamma}{\pi M} \sum_{m=1}^M \exp\left(-\Gamma \cdot \left|R[n] - \mathcal{S}^{(m)}\right|^2\right)\right] = -\frac{1}{N} \sum_{n=1}^N \log_2\left[\frac{e}{M} \sum_{m=1}^M \exp\left(-\Gamma \cdot \left|R[n] - \mathcal{S}^{(m)}\right|^2\right)\right],$$
(7)

where the " \approx " sign can be replaced by "=" as $N \to \infty$.

Moreover, the derivative of $C_{\rm RF}$ with respect to Γ indicates the sensitivity of channel capacity to SNR changes, expressed

$$\frac{\partial C_{\rm RF}}{\partial \Gamma} = \frac{\sum_{n=1}^{N} \left[\frac{\sum_{m=1}^{M} \left| R[n] - \mathcal{S}^{(m)} \right|^2 \exp\left(-\Gamma \cdot \left| R[n] - \mathcal{S}^{(m)} \right|^2\right)}{\ln 2 \cdot \sum_{m=1}^{M} \exp\left(-\Gamma \cdot \left| R[n] - \mathcal{S}^{(m)} \right|^2\right)} \right]}{N}.$$
 (8)

B. DCMC Capacity of an ACO-OFDM System

Recall from Sec. II that in ACO-OFDM only K/4 symbols can be conveyed by a total of K subcarriers. Therefore, the channel capacity contribution can be divided into two parts:

- The 3K/4 subcarriers loaded either with the conjugate of the transmitted symbols or with the FD-product of the TD clipping distortion, whose capacity-contribution is 0, because they provide no new information, and
- The K/4 subcarriers loaded with the desired transmitted symbols.

The K/4 FD subcarriers in the second part may be viewed as isolated RF carriers, where (4) can be applied. Therefore, the capacity of an ACO-OFDM system is given by

$$C_{\rm ACO}(\Gamma) = \frac{K/4}{K} C_{\rm RF}(\Gamma) + \frac{3K/4}{K} \cdot 0 = \frac{1}{4} C_{\rm RF}(\Gamma), \quad (9)$$

where the proportionality coefficient 1/4 represents the reduced bandwidth efficiency.

Since the total signal power P_{ACO} is equally spread across the K/4 transmitted subcarrier symbols (25%), the K/4conjugate symbols (25%) and the K/2 distortion symbols (50%), we have

$$\Gamma_{\rm ACO} = \frac{E_s}{\frac{1}{2}N_0} = \frac{\frac{1}{4}P_{\rm ACO}}{\frac{K/4}{K}\frac{1}{2}N_0} = \frac{P_{\rm ACO}}{\frac{1}{2}N_0},$$
(10)

where the factor $\frac{1}{2}$ in the denominator is because the imaginary part of the complex-valued TD noise has no effect on the performance.

C. Power Relationships in LACO-OFDM

Without loss of generality, we denote the electric signal power of the *l*th layer in LACO-OFDM as P_l . The TD signal obeys a one-sided truncated Gaussian distribution [21] with the PDF given by

$$PDF(x) = \frac{1}{2}\delta(x) + \frac{1}{\sqrt{2\pi\sigma}}\exp\left[-\frac{x^2}{2\sigma^2}\right]u(x), \quad (11)$$

where $\delta(\cdot)$ and $u(\cdot)$ are the Dirac delta function and Heaviside step function, respectively, while σ^2 is the variance of the signal before truncation. The power of a layer is then represented as

$$P_l = \int_{-\infty}^{\infty} x^2 \cdot \text{PDF}(x) \, \mathrm{d}x = \frac{1}{2}\sigma^2, \qquad (12)$$

because the truncation cuts half of the power. Furthermore, the mean and variance of a layer's signal can be expressed using P_l as

$$\mathbb{E}[s_l] = \int_{-\infty}^{\infty} x \cdot \text{PDF}(x) \, dx = \frac{\sigma}{\sqrt{2\pi}} = \sqrt{\frac{P_l}{\pi}},$$
$$\mathbb{D}[s_l] = \int_{-\infty}^{\infty} (x - \mathbb{E}[s_l])^2 \cdot \text{PDF}(x) \, dx \qquad (13)$$
$$= \frac{\pi - 1}{2\pi} \sigma^2 = \left(1 - \frac{1}{\pi}\right) P_l.$$

5

 TABLE I

 COMPOSITION OF AN LACO-OFDM SIGNAL SHOWING THE NUMBER OF

SUBCARRIERS (\mathcal{N}) AND AVERAGE SYMBOL POWER (\mathcal{P}) OF THE FOUR PARTS OF EACH LAYER: DESIRED TRANSMITTED SYMBOLS (TX),

CONJUGATE SYMBOLS (CONJ.), CLIPPING DISTORTIONS OF THE CURRENT LAYER (DIST.) AND IDLE SUBCARRIERS AFTER CLIPPING (IDLE).

Layer	Layer	TX or Conj.		Dist.		Idle	
Index	Power	\mathcal{N}	\mathcal{P}	\mathcal{N}	\mathcal{P}	\mathcal{N}	\mathcal{P}
1	P_1	K/4	P_1	K/2	P_1	0	0
2	P_2	K/8	$2P_2$	K/4	$2P_2$	K/2	0
3	P_3	K/16	$4P_3$	K/8	$4P_{3}$	3K/4	0
l	P_l	$\frac{K}{2l+1}$	$2^{l-1}P_l$	$\frac{K}{2l}$	$2^{l-1}P_l$	K -	0
		2011		2*	-	$\frac{K}{2^{l-1}}$	

The overall electric signal power P_{LACO} could be expressed by its mean and variance as

$$P_{\text{LACO}} = \mathbb{D}[s] + (\mathbb{E}[s])^2, \qquad (14)$$

where both the mean and variance are the sum of their L constituent layers, given by:

$$P_{\text{LACO}} = \left(\sum_{l=1}^{L} \mathbb{D}[s_l]\right) + \left(\sum_{l=1}^{L} \mathbb{E}[s_l]\right)^2$$
$$= \left[\sum_{l=1}^{L} \left(1 - \frac{1}{\pi}\right) P_l\right] + \left(\sum_{l=1}^{L} \sqrt{\frac{P_l}{\pi}}\right)^2$$
$$= \left(1 - \frac{1}{\pi}\right) \sum_{l=1}^{L} P_l + \frac{1}{\pi} \left(\sum_{i=1}^{L} \sum_{j=1}^{L} \sqrt{P_i} \sqrt{P_j}\right)$$
$$= \sum_{l=1}^{L} P_l + \frac{2}{\pi} \sum_{i \neq j} \sqrt{P_i P_j}.$$
(15)

D. DCMC Capacity of a LACO-OFDM System

Table I shows the composition of each layer of a LACO-OFDM signal. On the *l*th layer of a LACO-OFDM scheme, only $\frac{K}{2^{l+1}}$ information-earning symbols can be transmitted, complemented by $\frac{K}{2^{l+1}}$ subcarriers for themselves, and another $\frac{K}{2^{l+1}}$ subcarriers for their conjugates, as well as by the $\frac{K}{2^{l}}$ additional subcarriers occupied by the FD-products of the TD clipping distortion. The power allocated to the *l*th layer shall be (statistically) equally shared among these $\frac{K}{2^{l-1}}$ subcarriers, which results in $2^{l-1}P_l$ for each subcarrier. The remaining $\left(1-\frac{1}{2^{l-1}}\right)K$ subcarriers are left empty, having zero power.

Given a sufficiently high SNR, the receiver can be expected to fully cancel out the TD-clipping distortions with the help of forward error correction codes (FEC) [22]. When detecting the *l*th layer at the receiver, its SNR Γ_l would be calculated using the power of the subcarriers loaded with the symbols, yielding

$$\Gamma_l = \frac{2^{l-1} P_l}{N_0/2}.$$
(16)

For LACO-OFDM, its first layer signal is constituted by an ACO-OFDM signal. As a result, the capacity contribution of LACO-OFDM from its first layer is:

$$C_1(\Gamma_1) = C_{\rm ACO}(\Gamma_1) = \frac{1}{4}C_{\rm RF}(\Gamma_1).$$
 (17)

Similarly, for the second and higher layer signals, their transmission rate contribution can be written as

$$C_{l}(\Gamma_{l}) = \frac{1}{2^{l-1}} C_{\rm ACO}(\Gamma_{1}) = \frac{1}{2^{l+1}} C_{\rm RF}(\Gamma_{l}).$$
(18)

Therefore, the overall capacity of a LACO-OFDM system having a total of L layers can be written as

$$C_{\rm LACO} = \sum_{l=1}^{L} C_l(\Gamma_l) = \frac{1}{2^{l+1}} C_{\rm RF}(\Gamma_l).$$
(19)

Explicitly, C_{LACO} is a function of the individual SNR of each layer $(\Gamma_1, \Gamma_2, \ldots, \Gamma_L)$, which is in turn a function of the power allocated to each layer (P_1, P_2, \ldots, P_L) , subject to the constraint

$$0 \le P_l \le P_{\text{LACO}}, \quad \forall \ l,$$
and (15).
(20)

IV. CAPACITY MAXIMIZATION FOR TWIN-LAYER LACO-OFDM

In this section, the total power and capacity of a twinlayer LACO-OFDM system, *i.e.* $P_{\rm LACO}^{(2)}$ and $C_{\rm LACO}^{(2)}$, represent $P_{\rm LACO}$ and $C_{\rm LACO}$, respectively.

A. Capacity of Twin-Layer LACO-OFDM

Let us consider a LACO-OFDM system consisting of 2 layers only and define the power sharing factor α ($0 \le \alpha \le 1$) as the specific fraction of the total power belonging to layer 1. Naturally, the second layer has then $(1 - \alpha)$ portion of the power, *i.e.* we have

$$\frac{P_1}{P_2} = \frac{\alpha}{1-\alpha}.$$
(21)

Substituting this into (15), we arrive at

$$P_{\text{LACO}} = P_1 + P_2 + \frac{2}{\pi}\sqrt{P_1P_2}$$

= $P_1 + \frac{1-\alpha}{\alpha}P_1 + \frac{2}{\pi}\sqrt{P_1 \cdot \frac{1-\alpha}{\alpha}P_1}$ (22)
= $P_1\left(\frac{1}{\alpha} + \frac{2}{\pi}\sqrt{\frac{1-\alpha}{\alpha}}\right).$

Therefore, P_1 can be represented as

$$P_1 = \frac{\alpha \cdot P_{\text{LACO}}}{1 + \frac{2}{\pi}\sqrt{\alpha(1-\alpha)}}.$$
(23)

Similarly,

$$P_2 = \frac{(1-\alpha) \cdot P_{\text{LACO}}}{1 + \frac{2}{\pi} \sqrt{\alpha(1-\alpha)}}.$$
(24)

For a given power constraint P_{LACO} and noise power N_0 , the overall channel SNR of LACO-OFDM is defined as $\Gamma_{\text{LACO}} = P_{\text{LACO}}/N_0$. Using (16), the corresponding SNR of each of the two layers becomes

$$\Gamma_1 = \frac{P_1}{N_0/2} = \frac{\alpha \cdot \Gamma_{\text{LACO}}}{1 + \frac{2}{\pi}\sqrt{\alpha(1-\alpha)}},$$
 (25a)

and
$$\Gamma_2 = \frac{2P_2}{N_0/2} = \frac{2(1-\alpha) \cdot \Gamma_{\text{LACO}}}{1 + \frac{2}{\pi} \sqrt{\alpha(1-\alpha)}}.$$
 (25b)

Note that the layer SNRs defined in (25) can be treated as a function of both the overall SNR Γ_{LACO} and the power sharing ratio α .

In this way, the overall capacity of this twin-layer LACO-OFDM system can be written according to (19) as

$$C_{\text{LACO}} = C_1(\Gamma_1) + C_2(\Gamma_2) = \frac{C_{\text{RF}}(\Gamma_1)}{4} + \frac{C_{\text{RF}}(\Gamma_2)}{8}.$$
 (26)

The chain rule of functions indicates that C_{LACO} shall also be a function of Γ_{LACO} and α . Therefore, the maximum throughput at a given SNR Γ can be determined by solving the following problem:

$$\max_{\alpha} \quad C_{\text{LACO}}(\Gamma_{\text{LACO}}, \alpha)$$
s.t. $0 \le \alpha \le 1$ (27)
and (22).

B. Characteristics of C_{LACO}

1) Existence of Maxima: For a given Γ , C_{LACO} is nonnegative by definition, having a lower bound of zero. On the other hand, the DCMC capacity is upper bounded by the general CCMC capacity [6] of

$$0 \le C_{\text{LACO}}(\Gamma, \alpha) \le \log_2(1+\Gamma), \quad \forall \alpha.$$
 (28)

Since C_{LACO} is formed of elementary functions, it is also continuous within $\alpha \in [0, 1]$. According to the extreme value theorem [31], at least one maximum must be attained by C_{LACO} for any given Γ within the interval $\alpha \in [0, 1]$.

2) Monotonicity of SNRs: If we take the partial derivative of C_{LACO} in (26) with respect to α , we have

$$\frac{\partial C_{\text{LACO}}}{\partial \alpha} = \frac{\partial}{\partial \alpha} \frac{C_{\text{RF}}(\Gamma_1)}{4} + \frac{\partial}{\partial \alpha} \frac{C_{\text{RF}}(\Gamma_2)}{8}$$
$$= \frac{1}{4} \underbrace{\frac{\partial C_{\text{RF}}}{\partial \Gamma_1}}_{\text{(c1)} \text{(c2)}} \underbrace{\frac{\partial \Gamma_1}{\partial \alpha}}_{\text{(d)}} + \frac{1}{8} \underbrace{\frac{\partial C_{\text{RF}}}{\partial \Gamma_2}}_{\text{(d1)} \text{(d1)}} \underbrace{\frac{\partial \Gamma_2}{\partial \alpha}}_{\text{(d)}}.$$
(29)

Since the channel capacity is always monotonically nondecreasing vs. the SNR [6], we have

$$\frac{\partial C_{\rm RF}}{\partial \Gamma_1} \ge 0, \quad \text{and} \quad \frac{\partial C_{\rm RF}}{\partial \Gamma_2} \ge 0.$$
 (30)

Using (25), the partial derivative of Γ_1 with respect to α is

$$\frac{\partial \Gamma_1}{\partial \alpha} = \frac{\partial}{\partial \alpha} \left(\frac{\alpha \cdot \Gamma_{\text{LACO}}}{1 + \frac{2}{\pi} \sqrt{\alpha (1 - \alpha)}} \right)$$
$$= \frac{\pi \left(\alpha + \pi \sqrt{(1 - \alpha)\alpha} \right) \Gamma_{\text{LACO}}}{\sqrt{(1 - \alpha)\alpha} \left(2\sqrt{(1 - \alpha)\alpha} + \pi \right)^2},$$
(31)

where C_{LACO} is locally treated as a positive constant. Symbolic analysis of (31) in Sec. IV-D shows that $\frac{\partial \Gamma_1}{\partial \alpha}$ is always positive within $\alpha \in [0, 1]$, with a minimum of $0.7241 \cdot \Gamma_{\text{LACO}} > 0$ at $\alpha = 0.3074$. Similarly, the partial derivative of Γ_2 with respect to α is

$$\frac{\partial\Gamma_2}{\partial\alpha} = -\frac{2\pi\left(1 - \alpha + \pi\sqrt{(1 - \alpha)\alpha}\right)\Gamma_{\text{LACO}}}{\sqrt{(1 - \alpha)\alpha}\left(2\sqrt{(1 - \alpha)\alpha} + \pi\right)^2},\qquad(32)$$

which is always negative within $\alpha \in [0, 1]$ having a maximum of $-1.4483\Gamma_{\text{LACO}} < 0$ at $\alpha = 0.6926$. Therefore, upon referring to (29), we have

$$(c) = \frac{1}{4} \frac{\partial C_{\rm RF}}{\partial \Gamma_1} \frac{\partial \Gamma_1}{\partial \alpha} \ge 0, \qquad (33a)$$

and
$$(d) = \frac{1}{8} \frac{\partial C_{\rm RF}}{\partial \Gamma_2} \frac{\partial \Gamma_2}{\partial \alpha} \le 0.$$
 (33b)

3) Maximum of C_{LACO} : As α approaches 0 from the right hand side, *i.e.* for $\alpha \to 0^+$, the majority of the power would be assigned to layer 2 according to (21), resulting in $P_1 \rightarrow 0$ and in turn $\Gamma_1 \to 0$ (linear) or $\Gamma_1 \to -\infty$ (dB). Therefore, (c1) in (29) tends to plus infinity according to Sec. III-A, while (c2) is a smaller value based on Γ_{LACO} . In this case, we have

$$(c) = \frac{1}{4}(c1) \cdot (c2) > -\frac{1}{8}(d1) \cdot (d2) = -(d),$$
 (34)

which yields

$$\left. \frac{\partial C_{\text{LACO}}}{\partial \alpha} \right|_0 > 0. \tag{35}$$

By symmetry, when $\alpha = 1$, part (d) in (29) obeys

$$\left. \frac{\partial C_{\text{LACO}}}{\partial \alpha} \right|_1 < 0. \tag{36}$$

According to Bolzano's theorem [31], due to having opposite sign for $\frac{\overline{\partial}C_{\text{LACO}}}{\partial\alpha}$ at the two edges, we arrive at

$$\exists \alpha^* \in [0,1], \text{ s.t. } \left. \frac{\partial C_{\text{LACO}}}{\partial \alpha} \right|_{\alpha^*} = 0.$$
 (37)

As it will be shown in the next Section, $\frac{\partial C_{\text{LACO}}}{\partial \alpha}$ is actually monotonically decreasing throughout the interval $\alpha \in [0, 1]$. Hence, the maximum of C_{LACO} for a particular Γ is obtained at $\alpha = \alpha^*$.

C. Maximum Search

Here, we propose an algorithm for finding the maximum of $C_{\rm LACO}$ for any given Γ , as well as the corresponding optimum α^* .

As seen in Alg. 1, we commence by entering the modulation order M and the overall channel SNR Γ_{LACO} , as well as the number of Monte-Carlo simulations N used for approximating the capacity and a decision threshold ϵ to determine if the stationary point of C_{LACO} is sufficiently accurate.

A binary search philosophy is adopted to find the optimum α^* . A pair of variables, p and q, are employed as the left and right search boundaries, having initial values of 0 and 1, respectively. The testing point of α is their average $\bar{\alpha} =$ $\frac{p+q}{2}$. As elaborated on before, the optimum value α^* is the stationary point of C_{LACO} . Therefore, a subroutine is provided for calculating the derivative of C_{LACO} at α_0 .

The program commences by calculating the SNR $\Gamma_1(\alpha)$ and $\Gamma_2(\alpha)$ of each layer at the initial $\bar{\alpha}$, using their corresponding relationships with α presented in (25). These two SNR values are subsequently substituted into the partial derivatives of the capacity expression with respect to the layer SNR formula, which is provided in (8) by differentiating (7). This leads to the value of (c1) and (d1) in (29). Meanwhile, $\bar{\alpha}$ is also

Algorithm 1 Power sharing in twin-layer LACO-OFDM

Input: M, Γ_{LACO} , N, ϵ **Output:** α^* , C^*_{LACO}

1: p := 0, q := 1;2: repeat

3: $\bar{\alpha} := (p+q)/2,$

Calculate $\Gamma_1(\bar{\alpha})$ and $\Gamma_2(\bar{\alpha})$ using (25), 4:

- Calculate $\frac{\partial C_{\text{LACO}}}{\partial \Gamma_1} \Big|_{\bar{\alpha}}$ and $\frac{\partial C_{\text{LACO}}}{\partial \Gamma_2} \Big|_{\bar{\alpha}}$, by substituting $\Gamma_1(\bar{\alpha})$ and $\Gamma_2(\bar{\alpha})$ into (8), respectively, Calculate $\frac{\partial \Gamma_1}{\partial \alpha} \Big|_{\bar{\alpha}}$ using (31) and $\frac{\partial \Gamma_2}{\partial \alpha} \Big|_{\bar{\alpha}}$ using (32), Calculate $\frac{\partial C_{\text{LACO}}}{\partial \alpha} \Big|_{\bar{\alpha}}$ at α by substituting the above 4 terms into (20). 5:
- 6:
- 7: terms into (29);

8: **if**
$$\frac{\partial C_{\text{LACO}}}{\partial \alpha} \Big|_{\alpha = \bar{\alpha}} > 0$$
 then
9: $p := \bar{\alpha}$.

else 10:

11:
$$q := \bar{c}$$

12: end if

13: **until** $\left|\frac{\partial C_{\text{LACO}}}{\partial r}\right| < \epsilon$;

14: return α^* $= \bar{\alpha}$

15: return
$$C^*_{\text{LACO}} = C_{\text{LACO}}(\alpha^*)$$

Fig. 5. The normalized derivatives of Γ_1 and Γ_2 in (31) and (32) vs. α .

substituted into (31) and (32) for obtaining (c2) and (d2) of (29), respectively. Having all components of (29) available, the algorithm becomes capable of providing $\frac{\partial C_{\text{LACO}}}{\partial \alpha}$ for the current $\bar{\alpha}$.

With the process of calculating $\frac{\partial C_{\text{LACO}}}{\partial \alpha}\Big|_{\bar{\alpha}}$ completed (corresponding to states 4-7 of Alg. 1), the problem can be simplified to finding the root of an equation. We have shown in Sec. IV-B that there is only a single root α^* and that $\frac{\partial C_{\text{LACO}}}{\partial \alpha}$ is monotonically decreasing from a positive value down to a negative value as a function of α . Therefore, by checking the sign of $\frac{\partial C_{\text{LACO}}}{\partial \alpha} \Big|_{\bar{\alpha}}$ at both ends of the search region of [0, 1]and gradually shrinking the searching window, the root can be eventually obtained within an accuracy of ϵ .

D. Numerical Results

Figure 5 plots the partial derivatives of Γ_1 and Γ_2 with respect to α based on (31) and (32), whose derivatives have

Fig. 6. α and SNR versus channel capacity of a twin-layer LACO-OFDM using 16QAM.

Fig. 7. Channel capacity and its derivative for twin-layer LACO-OFDM using 16QAM at SNR = 12 dB vs. the power sharing factor α .

been normalized by Γ_{LACO} . It is clearly shown that $\frac{\partial \Gamma_1}{\partial \alpha}$ is always positive, while $\frac{\partial \Gamma_2}{\partial \alpha}$ is always negative, in line with (35) and (36).

Figure 6 shows the channel capacity of twin-layer LACO-OFDM using 16QAM both vs. the overall SNR and vs. the power sharing factor α . Focusing our attention on the SNR axis, it is clear that the channel capacity converges to 1.5 bits/symbol upon increasing the SNR. This agrees with (26), because we have $\lim_{\Gamma \to \infty} C_{\text{RF}(\Gamma)} = 4$ for 16QAM. Similar trends can be found for all SNR values, namely that as α is increased from 0 to 1, the corresponding capacity first significantly increases and then decreases, albeit its maximum is not very pronounced.

A more clear view is provided in Fig. 7, where both the capacity as well as its derivative are plotted against α at

Fig. 8. Optimized capacity of twin-layer LACO-OFDM using Alg. 1 vs. the SNR.

SNR = 12 dB. The channel capacity increases up to the power sharing factor of $\alpha = 0.6841$, reaching a maximum of 1.3498 bits/symbol, before falling again. The corresponding derivative is monotonically decreasing and has a zero-crossing at $\alpha = 0.6841$, which verifies Alg. 1.

Meanwhile, Fig. 7 also indicates that the conventional power sharing strategy of $\frac{P_1}{P_2} = \frac{1}{2}$, corresponding to $\alpha = \frac{2}{3} \approx 0.6666$, yields a lower capacity. Up to this point, the derivative still remains positive, hence the capacity still increases with α . This trend will be further discussed in Sec. VI.

Moreover, the optimum channel capacity versus SNR for twin-layer LACO-OFDM associated with different modulation schemes is portrayed in Fig. 8.

V. CAPACITY MAXIMIZATION FOR MULTI-LAYER LACO-OFDM

In this section, we explore the capacity maximization problem of 3-layer LACO-OFDM systems, before generalizing it to multi-layer LACO-OFDM systems. In subsections A to C, the variables P_{LACO} , Γ_{LACO} and C_{LACO} represent the corresponding metrics of a 3-layer LACO-OFDM system, while in subsection D, they are for *L*-layer LACO-OFDM systems.

A. Capacity of 3-Layer LACO-OFDM

For 3-layer LACO-OFDM systems, the relationships between the power of the three layers can be reflected by introducing a pair of power sharing factors: α_1 and α_2 :

$$\frac{P_1}{P_2} = \frac{\alpha_1}{1 - \alpha_1}$$
 and $\frac{P_1}{P_3} = \frac{\alpha_2}{1 - \alpha_2}$, (38)

where $0 \le \alpha_1 \le 1$ and $0 \le \alpha_2 \le 1$.

Based on (15), the overall power of the 3-layer LACO-OFDM system can now be expressed purely in terms of P_1 , as seen in (39). Therefore, with the additional help of (38),

$$P_{\text{LACO}} = P_1 + P_2 + P_3 + \frac{2}{\pi} \left(\sqrt{P_1 P_2} + \sqrt{P_1 P_3} + \sqrt{P_2 P_3} \right)$$

= $P_1 + \frac{1 - \alpha_1}{\alpha_1} P_1 + \frac{1 - \alpha_2}{\alpha_2} P_1 + \frac{2}{\pi} \left(\sqrt{P_1 \cdot \frac{1 - \alpha_1}{\alpha_1} P_1} + \sqrt{P_1 \cdot \frac{1 - \alpha_2}{\alpha_2} P_1} + \sqrt{\frac{1 - \alpha_1}{\alpha_1} P_1 \cdot \frac{1 - \alpha_2}{\alpha_2} P_1} \right)$
= $P_1 \left[1 + \frac{1 - \alpha_1}{\alpha_1} + \frac{1 - \alpha_2}{\alpha_2} + \frac{2}{\pi} \left(\sqrt{\frac{1 - \alpha_1}{\alpha_1}} + \sqrt{\frac{1 - \alpha_2}{\alpha_2}} + \sqrt{\frac{(1 - \alpha_1)(1 - \alpha_2)}{\alpha_1 \alpha_2}} \right) \right]$
= $\frac{P_1}{\alpha_1 \alpha_2} \cdot \left[\alpha_1 + \alpha_2 - \alpha_1 \alpha_2 + \frac{2}{\pi} \left(\alpha_2 \sqrt{\alpha_1(1 - \alpha_1)} + \alpha_1 \sqrt{\alpha_2(1 - \alpha_2)} + \sqrt{\alpha_1 \alpha_2(1 - \alpha_1)(1 - \alpha_2)} \right) \right].$
(39)

the SNR of each layer can be expressed as

$$\Gamma_1 = \frac{P_1}{N_0/2} = \frac{\alpha_1 \alpha_2 \cdot \Gamma_{\text{LACO}}}{P^\star}, \qquad (40a)$$

$$\Gamma_2 = \frac{2P_2}{N_0/2} = \frac{2(1-\alpha_1)\alpha_2 \cdot \Gamma_{\text{LACO}}}{P^{\star}},$$
 (40b)

$$\Gamma_3 = \frac{4P_3}{N_0/2} = \frac{4\alpha_1(1-\alpha_2)\cdot\Gamma_{\text{LACO}}}{\mathbf{P}^{\star}},\qquad(40c)$$

where P^* was defined in (39), which is a function of both α_1 and α_2 . The overall DCMC capacity of 3-layer LACO-OFDM can then be expressed as the sum of the 3 layers' capacities:

$$C_{\text{LACO}} = C_1(\Gamma_1) + C_2(\Gamma_2) + C_3(\Gamma_3)$$

= $\frac{C_{\text{RF}}(\Gamma_1)}{4} + \frac{C_{\text{RF}}(\Gamma_2)}{8} + \frac{C_{\text{RF}}(\Gamma_3)}{16}.$ (41)

Apparently, for any given total SNR (Γ_{LACO}), C_{LACO} depends² on both α_1 and α_2 . Bearing this in mind, let us now study the associated capacity maximization problem.

B. Maximization of 3-Layer LACO-OFDM Capacity

The extreme values of the dual-variable function C_{LACO} will only occur at points, where its gradient equals zero. Therefore, the partial derivatives of C_{LACO} with respect to α_1 and α_2 are expressed as:

$$\frac{\partial C_{\text{LACO}}}{\partial \alpha_1} = \frac{1}{4} \frac{\partial C_{\text{RF}}}{\partial \Gamma_1} \frac{\partial \Gamma_1}{\partial \alpha_1} + \frac{1}{8} \frac{\partial C_{\text{RF}}}{\partial \Gamma_2} \frac{\partial \Gamma_2}{\partial \alpha_1} + \frac{1}{16} \frac{\partial C_{\text{RF}}}{\partial \Gamma_3} \frac{\partial \Gamma_3}{\partial \alpha_1},$$
(42a)

$$\frac{\partial C_{\text{LACO}}}{\partial \alpha_2} = \frac{1}{4} \frac{\partial C_{\text{RF}}}{\partial \Gamma_1} \frac{\partial \Gamma_1}{\partial \alpha_2} + \frac{1}{8} \frac{\partial C_{\text{RF}}}{\partial \Gamma_2} \frac{\partial \Gamma_2}{\partial \alpha_2} + \frac{1}{16} \frac{\partial C_{\text{RF}}}{\partial \Gamma_3} \frac{\partial \Gamma_3}{\partial \alpha_2}.$$
(42b)

The characteristics of C_{LACO} are similar to those of its twinlayer counterpart shown in Sec. IV-B, which is monotonically increasing and then decreasing within [0,1] for both α_1 and α_2 . The optimum point (α_1^*, α_2^*) can be found by solving

$$\operatorname{diag}\{\nabla C_{\mathrm{LACO}}(\alpha_1, \alpha_2)\} = \mathbf{0}.$$
(43)

 2 At the moment, all other variables, such as M and N, are treated as constants.

Note that

$$\frac{\partial \Gamma_1}{\partial \alpha_1} = \frac{\Gamma_{\text{LACO}}}{(\mathbf{P}^\star)^2} \left(\alpha_2 \mathbf{P}^\star - \alpha_1 \alpha_2 \frac{\partial \mathbf{P}^\star}{\partial \alpha_1} \right), \tag{44a}$$

$$\frac{\partial \Gamma_2}{\partial \alpha_1} = \frac{\Gamma_{\text{LACO}}}{(\mathbf{P}^\star)^2} \left(-2\alpha_2 \mathbf{P}^\star - \alpha_1 \alpha_2 \frac{\partial \mathbf{P}^\star}{\partial \alpha_1} \right), \tag{44b}$$

$$\frac{\partial \Gamma_3}{\partial \alpha_1} = \frac{\Gamma_{\text{LACO}}}{(\mathbf{P}^\star)^2} \left(4(1-\alpha_2)\mathbf{P}^\star - \alpha_1\alpha_2\frac{\partial \mathbf{P}^\star}{\partial \alpha_1} \right), \quad (44c)$$

where

and

$$\frac{\partial \mathbf{P}^{\star}}{\partial \alpha_{1}} = 1 - \alpha_{2} + \frac{2}{\pi} \sqrt{\alpha_{2}(1 - \alpha_{2})} + \frac{(1 - 2\alpha_{1})\left(\alpha_{2} + \sqrt{\alpha_{2}(1 - \alpha_{2})}\right)}{\pi \sqrt{\alpha_{2}(1 - \alpha_{2})}};$$
(44d)

$$\frac{\partial \Gamma_1}{\partial \alpha_2} = \frac{\Gamma_{\text{LACO}}}{(\mathbf{P}^\star)^2} \left(\alpha_1 \mathbf{P}^\star - \alpha_1 \alpha_2 \frac{\partial \mathbf{P}^\star}{\partial \alpha_2} \right), \tag{44e}$$

$$\frac{\partial \Gamma_2}{\partial \alpha_2} = \frac{\Gamma_{\rm LACO}}{(\mathbf{P}^{\star})^2} \left(2(1-\alpha_1)\mathbf{P}^{\star} - \alpha_1\alpha_2\frac{\partial \mathbf{P}^{\star}}{\partial \alpha_2} \right), \quad (44f)$$

$$\frac{\partial \Gamma_3}{\partial \alpha_2} = \frac{\Gamma_{\text{LACO}}}{(\mathbf{P}^{\star})^2} \left(-4\alpha_1 \mathbf{P}^{\star} - \alpha_1 \alpha_2 \frac{\partial \mathbf{P}^{\star}}{\partial \alpha_2} \right), \tag{44g}$$

where

$$\frac{\partial \mathbf{P}^{\star}}{\partial \alpha_2} = 1 - \alpha_1 + \frac{2}{\pi} \sqrt{\alpha_1 (1 - \alpha_1)} + \frac{(1 - 2\alpha_2) \left(\alpha_1 + \sqrt{\alpha_1 (1 - \alpha_1)}\right)}{\pi \sqrt{\alpha_2 (1 - \alpha_2)}}.$$
(44h)

Since α_1 appears in the expressions of (44e-44h) and α_2 in (44a-44d), a nested algorithm is required for solving (43).

As shown in Alg. 2, the search is conducted in the twinned directions: of α_1 and α_2 , respectively. The inner loop is detailed in Alg. 3, which takes a given value of $\bar{\alpha}_1$ and substitutes it into (42b), followed by finding the corresponding α_2 coordinate, where the zero-crossing occurs, using similar methods to those in Alg. 1. The outer loop of Alg. 2 then takes the returned value $\bar{\alpha}_2$ to determine whether a zero-crossing has also be found for (42a). If not, $\bar{\alpha}_1$ will be updated in a binary-search manner and forwarded to Alg. 3 for the corresponding new $\bar{\alpha}_2$. The process continues by checking and updating $\bar{\alpha}_1$ and $\bar{\alpha}_2$, until a zero-crossing occurs in both directions, thus reaching the stationary point.

Algorithm 2 Power sharing in 3-layer LACO-OFDM **Input:** $M, \Gamma_{\text{LACO}}, N, \epsilon$ **Output:** $\alpha_1^*, \alpha_2^*, C_{\text{LACO}}^*$ 1: $p_1 := 0, q_1 := 1$ 2: repeat $\bar{\alpha}_1 := (p_1 + q_1)/2,$ 3: Find $\bar{\alpha}_2$ under current $\bar{\alpha}_1$ using Alg. 3; 4: Calculate $\Gamma_l(\bar{\alpha}_1, \bar{\alpha}_2)$ for l = 1, 2, 3 using (40), 5: Calculate $\frac{\partial C_{\text{LACO}}}{\partial \Gamma_l}\Big|_{(\bar{\alpha}_1, \bar{\alpha}_2)}$ for l = 1, 2, 3 using (32), 6: $\label{eq:calculate} \text{ Calculate } \left. \frac{\partial \Gamma_l}{\partial \alpha_1} \right|_{\left(\bar{\alpha}_1,\bar{\alpha}_2\right)} \text{ for } l=1,2,3 \text{ using (44),}$ 7: Calculate $\frac{\partial C_{\text{LACO}}}{\partial \alpha_1}\Big|_{(\bar{\alpha}_1, \bar{\alpha}_2)}$ by substituting the above 6 8: terms into (42a); if $\frac{\partial C_{\text{LACO}}}{\partial x}$ 9: > 0 then $\bar{\partial}\alpha_1$ $\frac{1}{2}(\bar{\alpha}_1,\bar{\alpha}_2)$ 10: $p_1 := \bar{\alpha}_1,$ 11: else $q_1 := \bar{\alpha}_1,$ 12: end if 13: $\frac{\partial \alpha_1}{\partial \alpha_1}\Big|_{(\bar{\alpha}_1, \bar{\alpha}_2)} < \epsilon \text{ at } (\alpha_1, \alpha_2);$ 14: **until** $\frac{\partial C_{\text{LACO}}}{\partial c}$ 15: **return** $\alpha_1^* = \bar{\alpha}_1, \ \alpha_2^* = \bar{\alpha}_2$; 16: return $C_{\text{LACO}}^* = C_{\text{LACO}}(\alpha_1^*, \alpha_2^*)$;

Algorithm 3 Zero Crossing Finder for Eq. (42b)

1: $p_2 := 0, q_2 := 1;$ 2: repeat $\bar{\alpha}_2 := (p_2 + q_2)/2,$ 3: Calculate $\Gamma_l(\bar{\alpha}_1, \bar{\bar{\alpha}}_2)$ for l = 1, 2, 3 using (40), 4: Calculate $\frac{\partial C_{\text{LACO}}}{\partial \Gamma_l}$ at $\Gamma_l(\bar{\alpha}_1, \bar{\alpha}_2)$ for l = 1, 2, 3 using 5: (32),Calculate $\frac{\partial \Gamma_l}{\partial \alpha_2}\Big|_{(\bar{\alpha}_1, \bar{\bar{\alpha}}_2)}$ for l = 1, 2, 3 using (44), 6: Calculate $\frac{\partial C_{\text{LACO}}}{\partial \alpha_2}\Big|_{(\bar{\alpha}_1, \bar{\bar{\alpha}}_2)}$ 7: by substituting the above 6 terms into (42b); if $\left. \frac{\partial C_{\text{LACO}}}{\partial \alpha_2} \right|_{=} (\bar{\alpha}_1, \bar{\alpha}_2) > 0$ then 8: 9: $p_2 := \overline{\alpha_2},$ 10: else 11: $q_2 := \bar{\alpha_2},$ 12: end if ∂C_{LACO} 13: **until** $\partial \alpha_2$ $(\bar{\alpha}_1, \bar{\bar{\alpha}}_2)$ 14: return $\bar{\alpha}_2 = \bar{\bar{\alpha}}_2$

C. Numerical Results

In Fig. 9, we portray the channel capacity of a 3-layer LACO-OFDM system vs. its power sharing factors α_1 and α_2 , using 16QAM at an SNR of 12 dB. Observe that the capacity first increases and then decreases with respect to both α_1 and α_2 , resulting in a global peak in the middle.

To elaborate a little further, in Fig. 10 we provide crosssectional views of the capacity by slicing the 3D surface of Fig. 9 along α_1 and α_2 , respectively. The derivatives with respect to the corresponding variables are also depicted in the same figure. In Fig. 10a, the capacity peak can be found at

Fig. 9. Channel capacity of 3-Layer LACO-OFDM using 16QAM at SNR = 12 dB vs. α_1 and α_2 .

Fig. 10. Channel capacity of 3-layer LACO-OFDM extracted from Fig. 9 and its derivatives.

the zero crossing of its derivative, namely at $\alpha_1 = 0.701$. Fig. 10b is then sliced by the vertical plane at $\alpha_1 = 0.701$, leading to the same capacity peak at $\alpha_2 = 0.6841$, which in turn decides where to slice it for generating Fig. 10a. Since the capacity derivatives are zero in both directions at $(\alpha_1, \alpha_2) = (0.701, 0.6841)$, the peak constitutes a global capacity maximum.

To provide further insights, Fig. 11 depicts the optimum channel capacity versus SNR for 3-layer LACO-OFDM in conjunction with different modulation schemes.

D. Generalization of the Algorithm

Let us now continue by summarizing the optimum power sharing of 3-layer LACO-OFDM systems and by generalizing it for *L*-layer LACO-OFDM.

Fig. 11. Optimized DCMC capacity of 3-Layer LACO-OFDM vs. SNR using the proposed algorithm.

1) Let us establish the power sharing factors using $\alpha = [\alpha_1, \ldots, \alpha_l, \ldots, \alpha_{L-1}]$, and

$$\frac{P_1}{P_l} = \frac{\alpha_{l-1}}{1 - \alpha_{l-1}}, \quad 0 \le \alpha_{l-1} \le 1.$$
(45)

- 2) Let us then express the SNRs of each layer Γ_l in terms of the total SNR Γ_{LACO} and α , using (15) and (16).
- 3) Obtain the total capacity formula C_{LACO} using (19), and differentiate it with respect to every element of α .
- 4) Using an (L-1)-stage nested loop in the power-sharing algorithm to find the maximum of C_{LACO} , we carry out the following steps:
 - a) Fix the values of $\alpha_1, ... \alpha_{L-2}$ and substitute them into $\frac{\partial C_{\text{LACO}}}{\partial \alpha_{L-1}} = 0$. Find the root α_{L-1} using binary search within [0, 1] and return to its upper loop.
 - b) Sweep the value of α_{L-2} across its legitimate range and calculate the corresponding α_{L-1} each time, until $\frac{\partial C_{LACO}}{\partial \alpha_{L-2}} = 0$ is reached. Forward α_{L-1} and α_{L-2} to the upper loop.
 - c) Repeat this procedure until the top stage of the loop is reached and find the values of all elements in α so that we have diag{ ∇C_{LACO} } = 0.

VI. DISCUSSIONS

A. Comparison to Conventional Power Sharing Strategy

In previous contributions on LACO-OFDM [15], [21], [23], the "equal power per bit" strategy has been employed, where the same amount of power is assigned to all information bits in the system, regardless of their location in the layers. Explicitly, if the same modulation order is applied for all layers, each layer should have twice the energy of its directlyfollowing layer, because the former transmits twice the amount of information bits than the latter. This leads to a fixed $\alpha = \{\alpha_1, \alpha_2, \dots, \alpha_{L-1}\}$ vector, regardless of the channel SNR. According to (45), we have

$$\alpha_l = \frac{P_1}{P_1 + P_{l+1}} = \frac{2^l P_{l+1}}{2^l P_{l+1} + P_{l+1}} = 1 - \frac{1}{2^{l+1}}.$$
 (46)

Fig. 12. Capacity comparison for LACO-OFDM schemes using conventional and proposed power sharing algorithms. 16QAM modulation is used for all simulations.

In Fig. 12, we compare the capacity improvement attained by using the Algorithm proposed. Observe that the "equal power per bit" strategy is outperformed by the proposed one.

Specifically, at SNR = 12 dB, a beneficial capacity improvement of about 0.18 bits/symbol can be attained by 3-layer LACO-OFDM using 16QAM. From a different prospective, this can also be equivalently expressed as a 1.8 dB SNR gain, because the conventional strategy reaches the same capacity at a 1.8 dB higher SNR. By contrast, the difference for a twinlayer system remains negligible.

B. Adapting the Number of Layers

It may also be observed from Fig. 12 that the capacity curves do cross each other, before saturating for SNR \geq 20 dB. LACO-OFDM schemes having more layers have lower capacity in the low-SNR region before crossing all other curves. In the spirit of achieving the maximum capacity, we propose to adapt the number of layers based on the overall SNR.

In Fig. 13, an example is provided for 16QAM LACO-OFDM, where the number of layers ranges from 1 to 4, with 1 representing ACO-OFDM instead of LACO-OFDM. In this case, when the SNR is lower than 0.7303 dB, using the second layer is in fact detrimental, because the power has to be shared between two layers. Beyond that point, utilizing LACO-OFDM shows capacity benefits. The handover between 2- and 3-layer LACO-OFDM occurs at SNR = 6.0653 dB, where they have equal capacity, and for 3- and 4-layer it is at SNR = 10.4124 dB.

The transmitter would require the channel SNR to be fed back from the receiver to the transmitter and determine the number of layers to use, based on which interval of Fig. 13 the SNR lies in. It will then find the optimum power sharing strategy using our proposed algorithm, which can be represented by a look-up table.

Fig. 13. Adaptive layer number selection for maximum capacity in LACO-OFDM based on the SNR.

VII. CONCLUSIONS

The DCMC capacity of LACO-OFDM has been derived for a given number of layers relying on our power sharing strategy. The capacity formula was then used as our objective function to maximize the capacity by tuning the power sharing factors and the number of layers as well. Specific algorithms have been proposed for solving optimization problem with the help of partial derivatives. Recursive algorithms were designed for our systems having more than 2 layers. The numerical results show an up to 0.18 bits/symbol increase of the capacity upon adopting the proposed power sharing strategy instead of the conventional one for 4-layer LACO-OFDM. Finally, an adaptive scheme was conceived for maximizing the DCMC capacity of LACO-OFDM relying on adapting the number of layers depending on the SNR encountered.
