Abstract

Objective: To develop a manualised psychological treatment for tinnitus that could enhance audiologist usual care, and to test feasibility of evaluating it in a randomised controlled trial.

Design: Feasibility trial, random allocation of patients to manualised treatment or treatment as usual, and mixed-methods evaluation.

Study sample: Senior audiologists, and adults with chronic tinnitus.

Results: Recruitment reached 63% after 6 months (feasibility pre-defined as 65%). Only nine patients (47%) were retained for the duration of the trial. Patients reported that the treatment was acceptable and helped reassure them about their tinnitus. Audiologists reported mixed feelings about the kinds of techniques that are presented to them as 'psychologically informed'. Audiologists also reported lacking confidence because the training they had was brief, and stated that more formal supervision would have been helpful to check adherence to the treatment manual.

Conclusions: The study indicate potential barriers to audiologist use of the manual, and that a clinical trial of the intervention is not yet feasible. However, positive indications from outcome measures suggest that further development work would be worthwhile. Refinements to the manual are indicated, and training and supervision arrangements to better support audiologists to use the intervention in the clinic are required.

Trial Registration: [ISRCTN13059163](https://www.isrctn.com/ISRCTN13059163).

For Peer Review Only

1 **Background**

2 Tinnitus involves the perception of sound in the absence of any acoustic stimuli (Davis & El
3 Refaie, 2000), and is often associated with insomnia, hearing problems, depression, and
4 anxiety (Tyler & Baker, 1983; Pinto et al., 2014). Cognitive behaviour therapy (CBT) has
5 been trialled extensively, but evidence is largely limited to clinical trials where a psychologist
6 delivered it (Fuller et al., 2020; Hesser et al., 2011; Hoare et al., 2011). Some studies have
7 additionally included multiple disciplines such as clinical physicists in audiology, who
8 deliver elements of care that are informed by psychology (e.g. Cima et al., 2012). In the UK
9 most tinnitus care is delivered by audiologists. However, there is no standard protocol for
10 tinnitus management and various approaches to assessment and treatment are used (Hoare et
11 al., 2015). Most audiology departments offer management of hearing loss, use of sound
12 generators, and patient education. Only some departments have access to psychologists
13 (Gander et al., 2011) and there is no evidence for the effectiveness of psychological
14 interventions when delivered by audiologists (Hoare et al., 2011). If audiologists were to use
15 a psychologically informed treatment approach, this could lead to improved outcomes and a
16 more cost-effective service (Stockdale et al., 2017; Wan Suhailah et al., 2015).

17
18 The Department of Health (now the Department of Health and Social Care) (2009)
19 recommends that audiologists provide psychological therapies where psychologists are not
20 available. Furthermore, patients and clinicians agree that whether CBT delivered by
21 audiologists is an effective treatment for tinnitus is a priority research question (Hall et al.,
22 2013). To that end, and in accordance with Medical Research Council (MRC)
23 recommendations for developing and evaluating complex interventions (Craig et al., 2008),
24 we took a phased approach to developing an audiologist delivered intervention that was
25 'psychologically informed'. To begin with, components of psychological therapies for

1
2
3 26 tinnitus were catalogued in a scoping review (Thompson et al., 2017). The primary aim of
4
5 27 that scoping review was to catalogue components of psychological therapies which have been
6
7
8 28 used or tested by psychologists in a format that would inform the development of a
9
10 29 standardised audiologist-delivered psychological intervention. Twenty-five ‘themes’ of
11
12 30 components were identified including tinnitus education, psychoeducation, evaluation,
13
14 31 treatment rationale, treatment planning, problem solving, behavioural intervention, thought
15
16 32 identification, thought challenging, worry time, emotions, social comparison, interpersonal
17
18 33 skills, self-concept, lifestyle advice, acceptance and defusion, mindfulness, attention,
19
20 34 relaxation, sleep, sound enrichment, comorbidity, treatment reflection, relapse prevention,
21
22 35 and common therapeutic skills.
23
24
25
26
27
28

29 37 In the second development stage, consensus on which therapy components audiologists
30
31 38 should deliver as part of their usual care was derived in a three-round Delphi survey of
32
33 39 patients who have experienced tinnitus counselling or psychological therapy, and specialist
34
35 40 audiologists, hearing therapists, and psychologists, who had significant experience of using
36
37 41 counselling or psychotherapeutic techniques for tinnitus (Thompson et al., 2018). The Delphi
38
39 42 survey included all those components identified in the scoping review (Thompson et al.,
40
41 43 2017) and any additional components identified by our experts during the first round of the
42
43 44 survey. Components that typically reached consensus for inclusion were common therapeutic
44
45 45 skills such as Socratic questioning and active listening, which are common to different
46
47 46 therapeutic modalities, rather than specific techniques such as graded exposure therapy or
48
49 47 cognitive restructuring, which are unique to a cognitive behavioural orientation. There was
50
51 48 clear consensus also to use a psychological model of tinnitus rather than a neurophysiological
52
53 49 model in patient education.
54
55
56
57
58
59
60

1
2
3 51 Here we report the next stage of this work. The aims were to (1) manualise a low-intensity
4
5 52 audiologist-delivered psychologically informed intervention for tinnitus, and (2) evaluate
6
7 53 feasibility of delivering and evaluating the manualised intervention. The intervention was
8
9 54 delivered by NHS audiologists with prior experience in tinnitus management. The study
10
11 55 primarily considered feasibility of a clinical trial of the manualised intervention in terms of
12
13 56 the likely patient population, willingness of patients to receive/engage with the manualised
14
15 57 treatment, willingness of audiologists to recruit and randomise tinnitus patients to a trial, and
16
17 58 willingness of patients to be randomised. Secondary objectives considered qualitative
18
19 59 judgements on the acceptability of the intervention from audiologist and patient perspectives,
20
21 60 and the likely completeness of selected outcome measures in a randomised controlled trial
22
23 61 (RCT). It was our aim to embed good practice in patient and public involvement at all stages.
24
25
26
27
28
29
30

31 **Methods**

32
33 64 The protocol for this work has previously been published (Taylor et al., 2017), and is
34
35 65 summarised here.
36
37
38
39

40 **Development of the manual**

41
42 68 Manual development commenced with a one-day reference group meeting involving steering
43
44 69 group and study team members (patients, audiologists, hearing therapists, psychologists, and
45
46 70 researchers) to decide on which components to include, and how to incorporate them into a
47
48 71 manualised care protocol. It was agreed at this meeting that a working framework for the
49
50 72 manual would comprise the following sections: Rationale, Assessment, Education, Treatment
51
52 73 Planning/Goal Setting, Management/Self-Management, and Relapse Prevention. All 76
53
54 74 components for which consensus for inclusion was reached in the Delphi survey (Thompson
55
56 75 et al., 2018) were first considered for allocation under these headings. This was followed by a
57
58
59
60

1
2
3 76 discussion on whether any of the 84 components for which consensus was not reached should
4
5 77 be included (no component reached consensus to absolutely exclude) and if so, under which
6
7 78 headings they would be written into the manual. Decisions were based on (1) level of
8
9
10 79 agreement from the Delphi survey, (2) whether components had a good evidence-base,
11
12 80 theoretical cohesiveness, and, (3) what could realistically be included in a brief low-intensity
13
14 81 intervention delivered by audiologists given resource limitations and time-limited training.
15
16 82 Individual members of the team drafted specific sections of the manual in accordance with
17
18 83 their areas of expertise and according to consensus opinion on what features are typical of a
19
20 84 'good' treatment manual (McCulloch & McMurrin, 2007). The manual was then reviewed
21
22 85 and amended to reflect a 'whole' in terms of style, coherence, and theory.
23
24
25
26
27
28

29 87 The final manual included nine sections (see Supplemental Information 1 for the overview
30
31 88 contained in the manual) detailing background and overview of the manual, assessment
32
33 89 through a standardised interview, the rationale for psychologically informed treatment,
34
35 90 collaborative goal setting and treatment planning, tinnitus education, management/self-
36
37 91 management strategies, relapse prevention, a bibliography containing references related to the
38
39 92 intervention and further reading for the audiologist or patient, and appendices containing
40
41 93 materials used for training purposes. An accompanying 'toolkit' (listed in Supplemental
42
43 94 Information 2) of questionnaires, worksheets, and information leaflets was collated to support
44
45 95 use of the manual.
46
47
48
49
50

51 97 **Feasibility trial**

52
53 98 Ethical approval for the feasibility trial was granted by North West - Preston Research Ethics
54
55 99 Committee (reference: 16/NM/0047). The trial involved random allocation of tinnitus
56
57
58 100 patients who received psychologically informed treatment from an audiologist trained in the
59
60

1
2
3 101 use of the manual, or treatment as usual (TAU) from an audiologist who was not trained in or
4
5 102 aware of the content of the treatment manual (Figure 1). Patients were randomised using the
6
7 103 randomisation function in Microsoft Excel such that patients allocated to the greatest five
8
9 104 random numbers per site were allocated to TAU. A member of the research department not
10
11 105 involved in the trial performed randomisation. There was no blinding (to allocation) of the
12
13 106 researchers who collected or analysed the qualitative or quantitative data.
14
15
16
17
18

19 108 ***INSERT FIGURE 1 ABOUT HERE***
20
21
22
23

24 110 **Trial sites and training**

25
26 111 Patients were recruited at three sites, audiology/Ear, Nose and Throat (ENT) services situated
27
28 112 in (1) Nottingham University Hospitals NHS Trust, (2) Sherwood Forest Hospitals NHS
29
30 113 Foundation Trust, and (3) Derby Hospitals NHS Foundation Trust. The audiologists
31
32 114 delivering the psychological tinnitus intervention and TAU at each site were senior
33
34 115 audiologists with several years of experience of managing tinnitus. A 2-day workshop was
35
36 116 developed by AC and DF to train audiologists to deliver the manual. Training was designed
37
38 117 to be interactive by using a constructive alignment approach (Biggs, 2003). AC developed
39
40 118 lesson plans using the Race lecturer toolkit (Race, 2014) including learning outcomes for
41
42 119 each session; resources needed to deliver the session; and the structure, content and method
43
44 120 of delivery. One senior audiologist from each site received training in the use of the manual
45
46 121 during the workshop. Learning was assessed using the Teach-back technique (Meyer et al.,
47
48 122 2010).
49
50
51
52
53

54 123

56 124 **Participants**

1
2
3 125 The recruitment method targeted people with tinnitus attending each participating site for an
4
5 126 audiology assessment appointment as part of the NHS standard care. Following consultation
6
7
8 127 with six NHS audiology sites, it was estimated that on average recruitment of two eligible
9
10 128 patients per month per site was readily achievable. We therefore conservatively estimated
11
12 129 feasibility of a trial to reflect this and requested each site to recruit and randomise up to ten
13
14 130 patients within a 6 month period. For inclusion, patients were required to (1) be adults aged
15
16 131 18 and over, (2) have intellectual/cognitive capacity to provide informed consent, (3) have
17
18 132 sufficient mobility to attend clinics, (4) score ≥ 25 on the Tinnitus Functional Index (TFI;
19
20 133 Meikle et al., 2012), and (5) be willing to complete questionnaires and a semi-structured
21
22 134 interview about their experiences of taking part in the trial. Patients were excluded if they (1)
23
24 135 had tinnitus with a medically treatable origin, (2) were unable to communicate in English, (3)
25
26 136 had comorbid conditions (e.g. dementia) which meant they were unable to give informed
27
28 137 consent, or (4) had participated in other tinnitus management research between consenting
29
30 138 and the start of the intervention. No exclusions were made because of previous experience
31
32 139 with psychological services or medications taken. All patients were enrolled at or before their
33
34 140 first visit to audiology with a primary complaint of tinnitus.
35
36
37
38
39

40 141
41
42 142 A member of the research team (JAT) was responsible for recruitment at Site 1. At Site 2 and
43
44 143 Site 3, the local PI was delegated responsibility for recruitment, with infrastructure support
45
46 144 provided by the National Institute for Health Research (NIHR) Clinical Research Network.
47
48 145 JAT regularly monitored recruitment at Sites 2 and 3 and maintained regular email contact
49
50 146 with the local PIs to offer support where recruitment rate was lower than required. However,
51
52 147 no additional support was requested during the trial.
53
54
55

56 148

58 149 **Intervention**

59
60

1
2
3 150 Psychologically informed treatment was delivered according to the treatment manual. This
4
5 151 involved an average of 2.75 sessions (range = 1-3) delivered one-to-one by an audiologist
6
7 152 who attended the training workshop.
8
9

10 153

12 154 **Control**

14 155 Patients allocated to the control condition received TAU from an audiologist not trained in
15
16 156 psychological therapy and who had not received training in the manualised intervention.
17
18 157 TAU typically involved management of hearing loss, education and advice, lasting an
19
20 158 average of 1.5 sessions (range = 1-2).
21
22
23

24 159

26 160 **Outcomes**

28 161 Feasibility of a powered RCT was predefined as (1) a recruitment efficiency of at least 10%
29
30 162 of those screened, (2) recruitment of at least 65% of the overall target sample size, (3)
31
32 163 retention of 80% of patients who were randomised, (4) completion of 80% for the primary
33
34 164 outcome questionnaires, and (5) patient and clinician compliance to the manualised tinnitus
35
36 165 counselling.
37
38
39

40 166

42 167 Six questionnaire were completed at each time point. The TFI is a measure of tinnitus
43
44 168 symptom severity over the last 2 weeks. It has 25 items (e.g. "Did you feel IN CONTROL in
45
46 169 regard to your tinnitus?"), each with a 10-point scale. Scores are summed and divided by 2.5
47
48 170 to give a total possible score between 0 and 100. The eight factor TFI has very high internal
49
50 171 consistency ($\alpha = 0.97$) (Meikle et al., 2012). It has excellent reliability, stability over time,
51
52 172 and sensitivity to individual differences in tinnitus severity, although the auditory subscale
53
54 173 (three items) may not contribute to the overall score (Fackrell et al., 2018).
55
56
57
58
59
60

1
2
3 175 The Tinnitus Cognitions Questionnaire (TCQ; Wilson & Henry, 1998) consists of a series of
4
5 176 statements preceded by the words “I think” or “I tell myself,” (e.g., I think “if only the noise
6
7 177 would go away”). The first 13 items refer to negative thoughts and the second 13 items refer
8
9
10 178 to positive thoughts. Responses are marked on a five-point Likert scale from “never” = 0, to
11
12 179 “very frequently” = 4. Positive items are reverse scored to give a total score from 0-104. The
13
14 180 TCQ has a reliable two-factor structure and high internal consistency ($\alpha = 0.90$) (Handscomb
15
16
17 181 et al., 2017).

18
19 182

20
21 183 The Clinical Outcomes in Routine Evaluation - Outcome Measure (CORE-OM; Barkham et
22
23 184 al., 2006) is a 34-item (four factor) measure of global distress. Respondents indicate how
24
25 185 much each item (e.g. “I have felt optimistic about my future”) has applied to them over the
26
27 186 past week, using a 5-point Likert scale from “not at all” to “most or all of the time”. The
28
29
30 187 CORE-OM includes both positive and negative items (positive items being reverse scored) to
31
32 188 give a total score from 0–136. Initial validation of this four factor questionnaire found it to
33
34 189 have high internal consistency ($\alpha = 0.94$) (Evans et al., 2002), although validation in a
35
36 190 tinnitus population found that a three factor structure provided a better fit to the data
37
38 191 (Handscomb et al., 2016).

39
40 192

41
42
43 193 The Health Utilities Index 15Q (HUI; Furlong et al., 2001) is a 15 item measure of health-
44
45 194 related quality of life. Items are multiple choice with 5-6 rank-ordered response options.
46
47 195 Decision tables of response combinations are used to determine the health-state level for each
48
49 196 domain within the questionnaire, and then using the tables and a scoring algorithm, utility
50
51 197 scores for all attributes of health and an overall health-related quality of life score is
52
53 198 determined. Overall scores range from -0.36 –1.00, where 0 = “death” and 1 = “perfect
54
55 199 health”. Estimates of the reliability of the HUI vary considerably (Busija et al., 2011).
56
57
58
59
60

1
2
3 200
4
5
6 201 The Working Alliance Inventory (WAI; Horvath & Greenberg, 1989) provides a measure of
7
8 202 the quality of alliance within counselling. It contains 36 items (e.g. “I was worried about the
9
10 203 outcome of the sessions”) scored on a Likert scale from 1 (Never) to 7 (Always). The WAI
11
12 204 contains both positive and negative items, with negative items being reversed scored, giving a
13
14 205 possible range of scores from 36 to 252. Reliability of the three WAI scale scores appear to
15
16 206 be high ($\alpha = 0.92, 0.92, \text{ and } 0.89$ respectively) although two subscales (“Tasks” and “Goals”)
17
18 207 were very highly correlated ($r = .92$).
19
20
21
22 208

23
24 209 The Client Service Receipt Inventory (CSRI; Beecham & Knapp, 2001) is an adaptable form
25
26 210 used to collect information on the whole range of services and supports study participants
27
28 211 may use. It contains items such as “Please list any use of inpatients hospital services over the
29
30 212 last three months”.
31
32

33 213
34
35 214 After randomisation, and in advance of their first audiology appointment, patients completed
36
37 215 the baseline study questionnaires. Questionnaires were completed again immediately at the
38
39 216 end of treatment and at follow-up or 6 months after the commencement of treatment
40
41 217 (excluding the CSRI which was only completed at follow-up). In practice, some 6-month
42
43 218 follow-up questionnaires were completed before the end of treatment. Patients received one
44
45 219 reminder (telephone or email) to complete the follow-up questionnaires if they had not been
46
47 220 returned within 2 weeks of their due date.
48
49
50

51 221

52 222 **Treatment fidelity**

53
54 223 Treatment fidelity required that treatment components were all consistency administered
55
56 224 according to the manual. Audiologists recorded administration of treatment components in a
57
58
59
60

1
2
3 225 case report form held for each patient, and took part in semi-structured interviews after the
4
5 226 last patient had completed their treatment. Interviews were used to determine which
6
7 227 components of the manualised care they thought worked well, why, and which components
8
9 228 were not useful. Patients involved in the intervention group also took part in semi-structured
10
11 229 interviews to discuss their experiences of the intervention. JAT or DMT conducted interviews
12
13 230 approximately 4 weeks after the last patient appointment. Clinician interviews were
14
15 231 conducted after discharge of their final patient. Interviews were audio-recorded, transcribed
16
17 232 verbatim and analysed using a thematic analysis approach (Braun & Clarke, 2006). DMT,
18
19 233 DMW, and two patient representative members of the lead centre's Patient and Public
20
21 234 Involvement (PPI) panel conducted analysis of the qualitative data.
22
23
24
25
26
27
28

236 **Deviations from protocol**

237 We had originally planned that public research partners trained in interview techniques would
238 conduct patient interviews. However, this ultimately proved unworkable due to the Sponsor's
239 stipulation that they would need formal registration as volunteers with the NHS Trust for this
240 activity. The process for this, involving application and interviews, was deemed too time
241 consuming to be accommodated within the study timeline. We had also originally planned to
242 discuss emerging themes in two focus groups with audiologists and patients, to ensure that
243 the themes and any identified barriers and facilitators to treatment implementation and
244 maintenance of self-management were accurately representative of patient and audiologist
245 experience. However, given the unanticipated length of the treatment process at sites, there
246 was insufficient time for this to be included within the funding period.

247

248 **Results**

249 **Demographic and clinical characteristics**

1
2
3 250 Nineteen patients were recruited to the trial and randomised to manualised care (n = 11) or
4
5 251 TAU (n = 8). Demographic characteristics are reported in Table 1. Mean baseline TFI score
6
7 252 was 67.08 (SD=23.644). Seven patients scored 25-50 on the TFI, scores interpreted as
8
9 253 tinnitus being a significant problem with a possible need for treatment (Henry et al., 2014).
10
11 254 Eleven patients scored above 50, interpreted as tinnitus severe enough to qualify for treatment
12
13 255 that is more intensive. Demographic data were missing for one patient.

INSERT TABLE 1 ABOUT HERE

259 **Feasibility outcomes**

260 Participant flow is presented in Figure 1, and feasibility outcomes are presented in Table 2.
261 Patients were screened from September 2016 to April 2017 (maximum six months from first
262 screen at each site). At Site 1, all 10 participants were recruited within a 3 month period; at
263 Site 2 three patients were recruited within a 3 month period, two of whom were recruited on
264 the same day); at Site 3 six patients were recruited within a 7 week period, five of whom
265 were recruited within the same week).
266
267 Six-month follow-up occurred from April to September 2017. Recruitment efficiency of
268 those screened surpassed the feasibility target at Site 1 where 10 eligible patients were
269 enrolled from just 16 patients screened (63%), while the target was one enrolment for every
270 10 patients screened (10%). Recruitment efficiency was also met at Site 2, where 24 patients
271 were screened and three patients were recruited (13%). This difference in recruitment
272 efficiency is in part a consequence of different patient pathways; at Site 1 all patients were
273 referred by their GP to ENT, and from ENT onto audiology. At Site 2 some patients were
274 referred directly to audiology by their GP. Indeed 10 of the 24 patients screened at Site 2

1
2
3 275 were assessed by the audiologist as requiring referral to ENT or psychiatry and therefore not
4
5 276 eligible for the trial. Also at Site 2, one recruited patient failed to attend any further
6
7
8 277 appointments, and three patients screened as eligible declined to participate due to the time
9
10 278 commitments involved and geographical distance between home and the audiology service.
11
12 279 Site 3 did not return their screening records so we were unable to assess feasibility.
13

14
15 280

16
17 281 ***INSERT TABLE 2 ABOUT HERE***
18

19 282

20
21 283 Nineteen patients were recruited and consented to take part in the study; representing a total
22
23 284 recruitment of 63% (feasibility target was 65%). Site 1 surpassed the target for feasibility
24
25 285 with 100% recruitment. Site 2 recruited three patients (30%) and Site 3 recruited six (60%).
26
27
28 286

29
30 287 Nine out of 19 patients were retained in the trial until the end of treatment, representing a
31
32 288 retention rate of 47% (feasibility criterion was 80%). Reasons for discontinuation included
33
34 289 spontaneous remission (n = 1), identification of Alzheimer's disease (n = 1), trial site error in
35
36 290 allocating patients to treatment arms (n = 1), loss to follow-up (n = 2), declined to participate
37
38 291 further (n = 1), or commenced other treatment (n = 3).
39

40
41 292

42 293 **Effectiveness outcomes**

43 294

44 295 Completeness of questionnaire data is given in Table 2, and descriptive statistics are
45
46 296 presented in Table 3. TFI, TCQ, TCQ negative thoughts subscale, and CORE-OM scores
47
48 297 decreased between baseline and the end of treatment. TFI scores continued to decrease
49
50 298 between the end of treatment and 6-month-follow-up, whereas TCQ and CORE-OM scores
51
52 299 were maintained between the end of treatment and 6-month follow-up. TFI emotional distress
53
54 300 subscale scores increased between baseline and the end of treatment, but decreased below
55
56 301 baseline by 6-month-follow up. Patients and audiologists' scores on the WAI task, bond, and
57
58
59
60

1
2
3 302 goal subscales all increased between baseline and end of treatment. No adverse events or
4
5 303 adverse reactions were recorded during the trial.
6
7
8 304

9
10 305 ***INSERT TABLE 3 ABOUT HERE***
11
12 306

13 14 307 **Treatment fidelity and experience**

15
16 308 Six themes emerged from thematic analysis of interview transcripts: (1) acceptability of and
17
18 309 fidelity to treatment components, (2) factors affecting fidelity, (3) refining treatment
19
20 310 components, (4) factors affecting feasibility of wider implementation of treatment, (5)
21
22 311 training and supervision, and (6) measurement of tinnitus outcomes.
23
24 312

25
26 313 (1) Acceptability of and fidelity to treatment components.
27
28
29 314

30 314 Patients and audiologists use, acceptance of, and fidelity to the treatment components varied.
31
32 315

33 315 All audiologists reported that they actively promoted physical activity, and patients reported
34
35 316 that they engaged in physical activity during the trial, despite it temporarily increasing
36
37 317 awareness of tinnitus. Other components were not used consistently, e.g. one audiologist and
38
39 318 one patient (from different sites) stated that they did not formally set any goals for treatment,
40
41 319 thereby deviating from the treatment protocol:
42
43 320

44 320 *“We didn’t set any formal goals, it was just a case of, I would go away and see...*

45 321 *whether it’s got any worse or whether it got any better and in actual fact it’s stayed*

46 322 *about the same.” (Patient 2).*
47
48
49 323

50
51 323 Another audiologist explained that goal setting can be challenging without first engaging in
52
53 324 tinnitus education to explain to the patient that they cannot cure their tinnitus:
54
55
56
57
58
59
60

1
2
3 325 “... I find the preliminary bit of goal setting a bit difficult because you’ve got to start
4
5 326 by saying, ‘we can’t cure your tinnitus, so with that in your mind, what would you like
6
7 327 to do?’” (Audiologist 3).

9
10 328 All patients reported being reassured by receiving information about the causes, maintenance,
11
12 329 and change in tinnitus over time, and for some patients, education was considered sufficient
13
14 330 intervention. For many patients the cognitive behavioural model of tinnitus reflected their
15
16 331 personal experiences of tinnitus. Patients and audiologists also commented that the model
17
18 332 was understandable:

19
20
21 333 *I think [the cognitive behavioural model is] quite a nice one because it’s quite logical,*
22
23 334 *the language that it uses is fairly easy, is nothing too sort of technical or too medical*
24
25 335 *and you can [work] through [the manual] in a logical way.” (Audiologist 2)*

26
27
28 336 Relaxation was acceptable to audiologists although it was used sparingly and briefly in and
29
30 337 outside of appointments. Patients mostly reported using relaxation to improve sleep. Patients
31
32 338 and audiologists also highly valued the inclusion of education about sleep cycles in treatment.
33
34 339 Patients in the trial did not use sleep diaries, sleep monitoring devices were favoured,
35
36 340 although the principle of monitoring sleep to identify poor sleeping habits was maintained:

37
38
39 341 *“No, I’ve been using [a fitness watch and not the sleep diary] because that records in*
40
41 342 *quite reasonable detail the amount of sleep you’ve had.” (Patient 1)*

42
43
44 343 Cognitive techniques received mixed reviews. Some patients expressed an understanding of
45
46 344 avoidance as a mechanism of tinnitus-related distress and recognised when they were
47
48 345 engaging in avoidance behaviours:

49
50
51 346 *“I avoided noisy environments. So, like if friends invited me round for a party, I*
52
53 347 *always used to make excuses not to go...” (Patient 3)*

54
55
56 348 Audiologists also demonstrated an understanding of safety behaviours such as avoidance.
57
58 349 However, at least one felt unable to recognise avoidance consistently in various contexts:
59
60

1
2
3 350 *“Safety [avoidance] behaviours...seems very obvious when you read the words.... But*
4
5 351 *then actually when the patient starts talking about the things that they do and their*
6
7 352 *feelings and their attitudes and how they deal with things you don’t necessarily think,*
8
9
10 353 *‘that’s a safety behaviour’.” (Audiologist 1)*
11

12 354 At least one audiologist found thought challenging prompts included in the treatment manual
13
14 355 useful, but fidelity to the thought-challenging component varied, often limited to identifying
15
16 356 negative thoughts without challenging them:

17
18
19 357 *“I didn’t use the thought record sheets. I used the unhelpful thinking styles [material],*
20
21 358 *and patients do find this one quite useful and quite often they’ll point out, ‘yeah,*
22
23 359 *that’s me’, and so that helps us to address some of these thoughts.” (Audiologist 3)*
24
25

26 360 When thought challenging was used, audiologists either considered the technique ineffective,
27
28 361 or believed the benefit would only be short term:

29
30 362 *“Most of the time [patients] don’t [think of a more helpful realistic thought]. And I*
31
32 363 *don’t know whether that’s because I’m not enabled enough or whether they just can’t*
33
34 364 *do it.” (Audiologist 1)*
35
36

37 365 The attention, monitoring and acceptance component of the manual was used in treatment but
38
39 366 not consistently or as instructed in the manual. One audiologist introduced the concept of
40
41 367 mindfulness, and two used metaphors when they thought it would be acceptable to patients.
42
43 368 However, one patient reported their audiologist used metaphors as an imagination exercise
44
45 369 rather than as an (intended) defusion technique:

46
47
48 370 *“We didn’t go through too many metaphors, obviously the metaphors of aligning the*
49
50 371 *sounds of your tinnitus to natural sounds. We didn’t talk about particular river*
51
52 372 *banks.” (Patient 1)*
53
54
55
56
57
58
59
60

1
2
3 373 Finally, relapse prevention was not addressed according to the manual. Patients remembered
4
5 374 being advised to return if their symptoms worsened or if self-management using the
6
7
8 375 techniques learned during the treatment were not effective:

9
10 376 *“I don’t think [the audiologist] did [share the relapse prevention handout] actually,*
11
12 377 *no because I don’t think we got on to that point actually.” (Patient 1)*

13
14 378

15
16
17 379 (2) Factors affecting fidelity

18
19 380 Audiologists reported a lack of confidence in implementing treatment components including
20
21 381 relaxation, acceptance-based components, and goal setting. One suggested that rigid use of
22
23 382 the manual would impair the development of the therapeutic relationship, particularly for less
24
25 383 experienced audiologists, and in contrast, another felt that the manual would help less
26
27 384 experienced audiologists by providing a structure to follow. For one audiologist, confidence
28
29 385 reportedly augmented with increasing experience during the trial:

30
31 386 *“You’re always a little bit nervous to start with. However, I found that after the first*
32
33 387 *few appointments it’s just flown. You develop your own pattern in appointments and I*
34
35 388 *guess I developed a pattern very, very quickly and that’s because it was very intense*
36
37 389 *training...” (Audiologist 3)*

38
39
40 390 Patients sometimes resisted the use of treatment components such as thought challenging or
41
42 391 mindfulness. Audiologists stated their patients would report not having enough time to
43
44 392 engage with the treatment outside of appointments, or just believed that the treatment would
45
46 393 be unsuccessful. Audiologists also considered some treatment components were within the
47
48 394 scope of practice of psychologists or hearing therapists, but not theirs:

49
50 395 *“To me [thought challenging] is a logical skill and I don’t know that that’s my*
51
52 396 *leaning at all. To say to somebody, ‘well that thought you are having there is very*
53
54 397 *unhelpful’ ...if you’re a psychologist you could do that. But I can’t.” (Audiologist 1)*

1
2
3 3984
5 399 (3) Refining treatment components6
7 400 Patients and audiologists recommended changes to the manual. These included expanding the
8
9 401 physical exercise component to include lifestyle advice on diet and alcohol.10
11 402 *“That’s something that we do anyway so within the tinnitus therapy process we*
12
13 403 *always talk about lifestyle choices. So, physical exercise comes into that but we also*
14
15 404 *talk about things like diet, we might also talk about you know where patients are*
16
17 405 *maybe drinking excessively.” (Audiologist 3)*18
19 406 *“If they’ve taken up hobbies that have enabled them to be more distracted, sort of*
20
21 407 *reinforcing those things and said, ‘these are the things that you know are going to*
22
23 408 *enable you in the long term to sort of ignore your tinnitus and live with it happily’.”*
24
25 409 *(Audiologist 2)*26
27 410 One audiologist found that some patients’ lack of motivation was a barrier to their
28
29 411 engagement in the treatment and that a technique to improve motivation would be useful.30
31 412 *“It’s like how can we break this down...what happens when you can’t motivate a*
32
33 413 *patient... how do you tackle somebody who is clearly giving you excuses...? Cause*
34
35 414 *there’s a harsh way which is, ‘look, you’re just giving lots of excuses.’ But that’s not*
36
37 415 *the way to do it. That doesn’t help anybody. But then is it up to us to go into maybe*
38
39 416 *the deeper reasons why they’re doing that, is it a confidence issue [for example], and*
40
41 417 *it’s that thing that’s stopping that patient from getting better.” (Audiologist 3)*42
43 418 (4) Factors affecting feasibility of wider implementation of treatment44
45 419 Audiologists unanimously agreed the treatment did not lengthen the amount of time spent
46
47 420 with patients throughout their care. However, participation in the intervention arm of the trial
48
49 421 affected the usual appointment structure. For example, the audiologists delayed hearing aid
50
51 422 fitting to allow time to gather information about underlying mental health problems first.
52
53
54
55
56
57
58
59
60

1
2
3 423 Audiologists also thought that reducing the time between appointments could increase
4
5 424 treatment benefit:

6
7
8 425 “ [reducing] follow-up [from] about 12 .. to...6 weeks after the initial appointment...
9
10 426 works because patients either take on board everything you say or they struggle with
11
12 427 it and if you’ve kind of let them go for three months you’re almost back to square one
13
14 428 sometimes.” (Audiologist 1)

15
16
17 429 However, concern was expressed that such changes to appointment structure might not be
18
19 430 feasible in audiology services where resources are limited. Continuity of care, with patients
20
21 431 seeing the same audiologist throughout their care was also considered beneficial:

22
23
24 432 “.. some patients even though they are hearing aid patients, probably would benefit
25
26 433 from being fitted by the tinnitus audiologist rather than an [other] audiologist
27
28 434 because some of the reasoning behind why we’re fitting the hearing aid has to be
29
30 435 related to the tinnitus. And perhaps that was lost ...” (Audiologist 2)

31
32
33 436

34
35 437 (5) Training and supervision

36
37 438 Audiologists were introduced to the manual across 2 days of training. Although audiologists
38
39 439 valued the small group setting, the content of the 2 days was considered overwhelming.

40
41 440 Audiologists involved in the trial suggested that it might not be feasible to implement this
42
43 441 format outside of the trial for routine clinical practice:

44
45
46 442 “It was excellent, one-to-one with a group of experts, what else could you ask for?
47
48 443 ...Feasibility-wise, would that work in practice? Probably not.” (Audiologist 3)

49
50
51 444 Some audiologists recommended role-play to improve the training to provide practice and
52
53 445 feedback on techniques in a range of scenarios in order to help audiologists to understand
54
55 446 how components of the manual would work in practice. All audiologists felt that formal

1
2
3 447 supervision arrangement would be helpful to check adherence to the treatment manual.
4

5
6 448 However, audiologists also noted the lack of supervision within audiology:
7

8 449 *“In adult audiology, we work in a silo... we don't have anyone else except our*
9
10 450 *colleagues to turn to, we don't have any formal supervision like you would if you were*
11
12 451 *a therapist.” (Audiologist 3)*
13

14
15 452 The potential for the treatment manual to be used as a training tool for inexperienced
16

17 453 audiologists was raised repeatedly during interviews:
18

19 454 *“I found [the manual] quite useful in terms of training somebody new to sort of say,*
20
21 455 *‘do you want to delve a bit deeper, is there something in these questions that perhaps*
22
23 456 *is relevant for the patient you've got sat in front of you?” (Audiologist 2)*
24
25

26 457
27

28 458 (6) Measurement of tinnitus outcomes
29

30
31 459 Patients and audiologists recognised that all the domains measured by the TFI and TCQ could
32
33 460 be relevant to different patients, and no additional domains were identified as relevant that
34
35 461 were not measured in the trial. The TFI was favoured as an assessment tool by patients and
36
37 462 audiologists because of its broad coverage across tinnitus problem domains to enable
38
39 463 identification of relevant treatment options. However, one audiologist highlighted that some
40
41 464 patients conflate hearing loss and tinnitus when completing the TFI, which may limit its
42
43 465 ability to distinguish between tinnitus-related and hearing-related distress. Audiologists were
44
45 466 less familiar with the TCQ, although one appreciated it as a means to encourage patients to
46
47 467 recognise and talk about their negative thoughts about tinnitus:
48
49

50
51 468 *“Sometimes patients are quite reluctant to give [negative thoughts], some patients*
52
53 469 *don't like feelings, but to get them to write it down and to score it, you get a bit more*
54
55 470 *of an overview of about where they are and how severe really the tinnitus is and how*
56
57 471 *much it is affecting them psychologically. So that again I've not used that one [TCQ]*
58
59
60

1
2
3 472 *routinely but I do think that one is one that I would probably use for those patients*
4
5 473 *where I'm perhaps struggling to see how much is affecting them psychologically."*
6
7
8 474 *(Audiologist 2)*
9

10 475 Patients also welcomed the use of tinnitus questionnaires to monitor their improvement
11
12 476 during treatment:

13
14 477 *"It makes you start to realise how well you're doing and it gives you a chance to*
15
16 478 *measure that...how bad it is or how you're managing really well."* (Patient 2)
17
18

19 479 Patients and audiologists had different views on the difficulty of completing questionnaires.

20
21 480 Whereas audiologists perceived questionnaires to be accessible, patients thought that support
22
23 481 should be offered to complete any questionnaires:

24
25 482 *"When you give a questionnaire like this and just give it to somebody – and I was put*
26
27 483 *in another room to do it – I think there's an assumption made that everyone can do*
28
29 484 *that task."* (Patient 2)
30
31
32

33 485

34 35 486 **Discussion**

36
37 487 This study was the first to develop and assess feasibility of trialling an audiologist-delivered
38
39 488 low intensity psychological intervention for tinnitus. Ultimately, we aimed to provide an
40
41 489 evidenced-based, costed, manualised approach to tinnitus care that is attractive to
42
43 490 commissioners and represents a flexible and accessible tinnitus treatment. The feasibility trial
44
45 491 reported here determined that a manualised psychologically informed treatment was
46
47 492 acceptable to patients and audiologists, but that it is not yet feasible to test in a multi-site
48
49 493 effectiveness trial. Recruitment reached only 19 patients (63%) after 6 months, just short of
50
51 494 the 65% target for feasibility, while average retention for the duration of the trial reached
52
53 495 only nine patients (47%), very short of the 80% target for feasibility. Patient recruitment is
54
55 496 acknowledged to be one of the most difficult and least predictable elements of a clinical trial.
56
57
58
59
60

1
2
3 497 (Allen et al., 1998; Thoma et al., 2010; Sanchez et al., 2018). Here, performance varied
4
5 498 across the three sites. The best in terms of recruitment efficiency and recruitment rate was
6
7 499 Site 1, an audiology service based in a large teaching hospital where staff are supported to be
8
9
10 500 research active. Having a large pool of potentially eligible patients to draw on, as well as
11
12 501 engaging with audiologists who have previous experience in participating in RCTs, are
13
14 502 known factors that can help to achieve study targets for hearing trials (Sanchez et al., 2018).
15
16 503 In addition, a member of the research team was responsible for recruitment at Site 1, and did
17
18 504 not have to contend with the same clinic demands as PIs at the other sites. That said, the
19
20 505 pattern of recruitment would suggest all could have reached feasibility. Site 3 in particular
21
22 506 recruited five patients (50% of target) within a single week, suggesting competing demands
23
24 507 and/or a lack of engagement with the research, rather than low patient numbers, were barriers
25
26 508 to recruitment at that site. In contrast, Site 1 performed poorest in terms of patient retention
27
28 509 indicating that even experienced participating sites need a risk mitigation plan and regular
29
30 510 trial monitoring. We would concur with the recommendations suggested by Sanchez et al.
31
32 511 (2018) that a future RCT needs to ensure that it has sufficient resource to support a carefully
33
34 512 specified plan to promote recruitment and retention of tinnitus patients. Furthermore, based
35
36 513 on current findings, we would suggest that treatment fidelity could be improved and more
37
38 514 accurately monitored by (1) including an audiologist familiarisation phase of treatment
39
40 515 implementation before including patients in analyses, and (2) including direct in-session
41
42 516 observation of a random selection of treatment sessions using standardised fidelity evaluation
43
44 517 forms, based on the treatment manual.
45
46
47
48
49
50

51 518
52
53 519 From the Delphi survey (Thompson et al., 2018) we know that psychoeducation and common
54
55 520 therapeutic skills are considered more important than specific CBT techniques in
56
57 521 psychological tinnitus treatment. Patients and audiologists considered it essential to include
58
59
60

1
2
3 522 psychoeducation and common therapeutic skills (aimed at informing the patient and
4
5 523 conveying empathy) in psychological tinnitus treatment. Giving patients information about
6
7 524 common cognitive distortions was considered essential, but cognitive restructuring was not.
8
9
10 525 This pattern suggests that patients and audiologists understood the contribution of
11
12 526 maladaptive behaviours and negative thoughts to bothersome tinnitus, but did not think that
13
14 527 the audiologist's role should or could extend to managing patients' use of specific cognitive
15
16 528 behavioural techniques. This issue was further highlighted in the current trial. Interviews
17
18 529 revealed audiologists chose not to use certain psychological treatment components from the
19
20 530 manual because (1) they lacked confidence in using them as training was brief and
21
22 531 insufficient for them to learn how to implement them safely and effectively, (2) they thought
23
24 532 patients do not want to record, monitor, and challenge specific negative thoughts and
25
26 533 behaviours, and (3) they believed certain components would be ineffective. More work is
27
28 534 therefore required to consider what audiologists can and want to deliver either within their
29
30 535 current or a revised clinic and appointment structure, and what training and supervision
31
32 536 arrangements need to be in place for these skills to be developed, used, and maintained
33
34 537 throughout a clinical trial. Beyond feasibility and evaluation of effectiveness, it will also be
35
36 538 essential to explore how the intervention can be implemented into routine clinical practice,
37
38 539 which will involve further challenges such as organisational development, workplace cultures
39
40 540 and individual barriers (De Silva, 2015).

41
42 541
43
44 542 Similar issues are being faced in other areas. For example, there is emerging evidence that
45
46 543 CBT-enhanced voice therapy for functional dysphonia leads to greater improvement in
47
48 544 general well-being and distress (Miller, Deary, & Patterson, 2014), but as with the current
49
50 545 study there are open questions about how clinicians should be trained and supervised and
51
52 546 how cost-effective this approach may be. There are examples in other fields of how training
53
54
55
56
57
58
59
60

1
2
3 547 might be achieved on a large scale. Richmond et al. (2016) evaluated feasibility of an online
4
5 548 programme to train physiotherapists in the use of cognitive behavioural approaches to the
6
7
8 549 management of non-specific low back pain. They found an internet-based approach to
9
10 550 training to be equivalent to face-to-face group training in terms of retention of theoretical and
11
12 551 procedural knowledge. However, clinicians who received the face-to-face training showed
13
14 552 greater self-efficacy in delivering the assessment component of the therapy, were more
15
16 553 satisfied with their training, and were more 'psychosocially' rather than 'biomedically'
17
18 554 orientated after training, and by implication were more aligned with a cognitive behavioural
19
20 555 approach. Regardless, uptake of the treatment approach after training was similar across both
21
22 556 groups (about one third). Their conclusion, that there is a need to develop strategies for
23
24 557 training and support to deliver treatments that use cognitive behavioural approaches, read
25
26 558 relevant to all allied health professionals at this time. In the context of the current study,
27
28 559 issues such as the acceptability and preference for different training formats will need to be
29
30
31 560 explored.

32
33
34
35 561
36
37 562 Certain revisions to the TinMan study manual and training require consideration before it can
38
39 563 be subjected to further feasibility testing. These include additional information about tinnitus
40
41 564 and psychoeducation, including information about negative thought patterns and avoidant
42
43 565 behaviours. An appreciation of patient preference and need with respect to psychological
44
45 566 treatment components was also apparent in the current study. Specific cognitive behavioral
46
47 567 techniques tend to purposefully engage patients in initially unwanted, though temporary,
48
49 568 thoughts or emotional states. It is of importance to train audiologists in how to deal with these
50
51 569 challenges and ultimately make use of the patient-states resulting from these approaches. The
52
53 570 natural resistance and transferal of distress in both patients and audiologists when using these
54
55
56
57
58
59
60

1
2
3 571 techniques needs to be adequately covered in training that balances informed patient choice
4
5 572 and need.
6
7

8 573
9 574 **Conclusion**

10
11 575 What emerged most strongly from this study is that an audiologist-delivered low-intensity
12
13 576 psychological intervention is an acceptable approach to tinnitus management, but even very
14
15 577 experienced audiologists require more extensive training to ‘upskill’ in the use of
16
17 578 psychological treatment components. Audiologists involved in delivering the psychological
18
19 579 treatment reported that the amount of training was insufficient and lacked role-play and
20
21 580 feedback from a supervisor to increase understanding of how to deliver the treatment
22
23 581 effectively. This needs to be addressed before further testing. One potentially cost-effective
24
25 582 means of training audiologists may be to develop reusable learning objects, e.g. including
26
27 583 video recordings of role-play scenarios where an audiologist is using a set of psychological
28
29 584 techniques from the manual. Once training is addressed, the treatment may progress to further
30
31 585 feasibility testing. There has been recent discussion in the UK audiology community about
32
33 586 some form of compulsory continual professional development or qualification in tinnitus care
34
35 587 for practicing audiologists. The manual developed here, and the training resources that will
36
37 588 support its use, could potentially meet this perceived need.

814

815

1 **Background**

2 Tinnitus involves the perception of sound in the absence of any acoustic stimuli (Davis & El
3 Refaie, 2000), and is often associated with insomnia, hearing problems, depression, and
4 anxiety (Tyler & Baker, 1983; Pinto et al., 2014). Cognitive behaviour therapy (CBT) has
5 been trialled extensively, but evidence is largely limited to clinical trials where a psychologist
6 delivered it (Fuller et al., 2020; Hesser et al., 2011; Hoare et al., 2011). Some studies have
7 additionally included multiple disciplines such as clinical physicists in audiology, who
8 deliver elements of care that are informed by psychology (e.g. Cima et al., 2012). In the UK
9 most tinnitus care is delivered by audiologists. However, there is no standard protocol for
10 tinnitus management and various approaches to assessment and treatment are used (Hoare et
11 al., 2015). Most audiology departments offer management of hearing loss, use of sound
12 generators, and patient education. Only some departments have access to psychologists
13 (Gander et al., 2011) and there is no evidence for the effectiveness of psychological
14 interventions when delivered by audiologists (Hoare et al., 2011). If audiologists were to use
15 a psychologically informed treatment approach, this could lead to improved outcomes and a
16 more cost-effective service (Stockdale et al., 2017; Wan Suhailah et al., 2015).

17
18 The Department of Health (now the Department of Health and Social Care) (2009)
19 recommends that audiologists provide psychological therapies where psychologists are not
20 available. Furthermore, patients and clinicians agree that whether CBT delivered by
21 audiologists is an effective treatment for tinnitus is a priority research question (Hall et al.,
22 2013). To that end, and in accordance with Medical Research Council (MRC)
23 recommendations for developing and evaluating complex interventions (Craig et al., 2008),
24 we took a phased approach to developing an audiologist delivered intervention that was
25 'psychologically informed'. To begin with, components of psychological therapies for

1
2
3 26 tinnitus were catalogued in a scoping review (Thompson et al., 2017). The primary aim of
4
5 27 that scoping review was to catalogue components of psychological therapies which have been
6
7
8 28 used or tested by psychologists in a format that would inform the development of a
9
10 29 standardised audiologist-delivered psychological intervention. Twenty-five ‘themes’ of
11
12 30 components were identified including tinnitus education, psychoeducation, evaluation,
13
14 31 treatment rationale, treatment planning, problem solving, behavioural intervention, thought
15
16 32 identification, thought challenging, worry time, emotions, social comparison, interpersonal
17
18 33 skills, self-concept, lifestyle advice, acceptance and defusion, mindfulness, attention,
19
20 34 relaxation, sleep, sound enrichment, comorbidity, treatment reflection, relapse prevention,
21
22 35 and common therapeutic skills.
23
24
25
26
27
28

29 37 In the second development stage, consensus on which therapy components audiologists
30
31 38 should deliver as part of their usual care was derived in a three-round Delphi survey of
32
33 39 patients who have experienced tinnitus counselling or psychological therapy, and specialist
34
35 40 audiologists, hearing therapists, and psychologists, who had significant experience of using
36
37 41 counselling or psychotherapeutic techniques for tinnitus (Thompson et al., 2018). The Delphi
38
39 42 survey included all those components identified in the scoping review (Thompson et al.,
40
41 43 2017) and any additional components identified by our experts during the first round of the
42
43 44 survey. Components that typically reached consensus for inclusion were common therapeutic
44
45 45 skills such as Socratic questioning and active listening, which are common to different
46
47 46 therapeutic modalities, rather than specific techniques such as graded exposure therapy or
48
49 47 cognitive restructuring, which are unique to a cognitive behavioural orientation. There was
50
51 48 clear consensus also to use a psychological model of tinnitus rather than a neurophysiological
52
53 49 model in patient education.
54
55
56
57
58
59
60

1
2
3 51 Here we report the next stage of this work. The aims were to (1) manualise a low-intensity
4
5 52 audiologist-delivered psychologically informed intervention for tinnitus, and (2) evaluate
6
7 53 feasibility of delivering and evaluating the manualised intervention. The intervention was
8
9 54 delivered by NHS audiologists with prior experience in tinnitus management. The study
10
11 55 primarily considered feasibility of a clinical trial of the manualised intervention in terms of
12
13 56 the likely patient population, willingness of patients to receive/engage with the manualised
14
15 57 treatment, willingness of audiologists to recruit and randomise tinnitus patients to a trial, and
16
17 58 willingness of patients to be randomised. Secondary objectives considered qualitative
18
19 59 judgements on the acceptability of the intervention from audiologist and patient perspectives,
20
21 60 and the likely completeness of selected outcome measures in a randomised controlled trial
22
23 61 (RCT). It was our aim to embed good practice in patient and public involvement at all stages.
24
25
26
27
28
29
30

31 **Methods**

32
33 64 The protocol for this work has previously been published (Taylor et al., 2017), and is
34
35 65 summarised here.
36
37
38
39

40 **Development of the manual**

41
42 68 Manual development commenced with a one-day reference group meeting involving steering
43
44 69 group and study team members (patients, audiologists, hearing therapists, psychologists, and
45
46 70 researchers) to decide on which components to include, and how to incorporate them into a
47
48 71 manualised care protocol. It was agreed at this meeting that a working framework for the
49
50 72 manual would comprise the following sections: Rationale, Assessment, Education, Treatment
51
52 73 Planning/Goal Setting, Management/Self-Management, and Relapse Prevention. All 76
53
54 74 components for which consensus for inclusion was reached in the Delphi survey (Thompson
55
56 75 et al., 2018) were first considered for allocation under these headings. This was followed by a
57
58
59
60

1
2
3 76 discussion on whether any of the 84 components for which consensus was not reached should
4
5 77 be included (no component reached consensus to absolutely exclude) and if so, under which
6
7 78 headings they would be written into the manual. Decisions were based on (1) level of
8
9
10 79 agreement from the Delphi survey, (2) whether components had a good evidence-base,
11
12 80 theoretical cohesiveness, and, (3) what could realistically be included in a brief low-intensity
13
14 81 intervention delivered by audiologists given resource limitations and time-limited training.
15
16
17 82 Individual members of the team drafted specific sections of the manual in accordance with
18
19 83 their areas of expertise and according to consensus opinion on what features are typical of a
20
21 84 'good' treatment manual (McCulloch & McMurrin, 2007). The manual was then reviewed
22
23
24 85 and amended to reflect a 'whole' in terms of style, coherence, and theory.
25
26
27 86

28
29 87 The final manual included nine sections (see Supplemental Information 1 for the overview
30
31 88 contained in the manual) detailing background and overview of the manual, assessment
32
33 89 through a standardised interview, the rationale for psychologically informed treatment,
34
35 90 collaborative goal setting and treatment planning, tinnitus education, management/self-
36
37
38 91 management strategies, relapse prevention, a bibliography containing references related to the
39
40 92 intervention and further reading for the audiologist or patient, and appendices containing
41
42 93 materials used for training purposes. An accompanying 'toolkit' (listed in Supplemental
43
44 94 Information 2) of questionnaires, worksheets, and information leaflets was collated to support
45
46
47 95 use of the manual.
48
49
50 96

51 97 **Feasibility trial**

52
53
54 98 Ethical approval for the feasibility trial was granted by North West - Preston Research Ethics
55
56 99 Committee (reference: 16/NM/0047). The trial involved random allocation of tinnitus
57
58 100 patients who received psychologically informed treatment from an audiologist trained in the
59
60

1
2
3 101 use of the manual, or treatment as usual (TAU) from an audiologist who was not trained in or
4
5 102 aware of the content of the treatment manual (Figure 1). Patients were randomised using the
6
7 103 randomisation function in Microsoft Excel such that patients allocated to the greatest five
8
9 104 random numbers per site were allocated to TAU. A member of the research department not
10
11 105 involved in the trial performed randomisation. There was no blinding (to allocation) of the
12
13 106 researchers who collected or analysed the qualitative or quantitative data.
14
15
16
17
18

19 108 ***INSERT FIGURE 1 ABOUT HERE***
20
21
22
23

24 110 **Trial sites and training**

25
26 111 Patients were recruited at three sites, audiology/Ear, Nose and Throat (ENT) services situated
27
28 112 in (1) Nottingham University Hospitals NHS Trust, (2) Sherwood Forest Hospitals NHS
29
30 113 Foundation Trust, and (3) Derby Hospitals NHS Foundation Trust. The audiologists
31
32 114 delivering the psychological tinnitus intervention and TAU at each site were senior
33
34 115 audiologists with several years of experience of managing tinnitus. A 2-day workshop was
35
36 116 developed by AC and DF to train audiologists to deliver the manual. Training was designed
37
38 117 to be interactive by using a constructive alignment approach (Biggs, 2003). AC developed
39
40 118 lesson plans using the Race lecturer toolkit (Race, 2014) including learning outcomes for
41
42 119 each session; resources needed to deliver the session; and the structure, content and method
43
44 120 of delivery. One senior audiologist from each site received training in the use of the manual
45
46 121 during the workshop. Learning was assessed using the Teach-back technique (Meyer et al.,
47
48 122 2010).
49
50
51
52
53

54 123

56 124 **Participants**

57
58
59
60

1
2
3 125 The recruitment method targeted people with tinnitus attending each participating site for an
4
5 126 audiology assessment appointment as part of the NHS standard care. Following consultation
6
7
8 127 with six NHS audiology sites, it was estimated that on average recruitment of two eligible
9
10 128 patients per month per site was readily achievable. We therefore conservatively estimated
11
12 129 feasibility of a trial to reflect this and requested each site to recruit and randomise up to ten
13
14 130 patients within a 6 month period. For inclusion, patients were required to (1) be adults aged
15
16 131 18 and over, (2) have intellectual/cognitive capacity to provide informed consent, (3) have
17
18 132 sufficient mobility to attend clinics, (4) score ≥ 25 on the Tinnitus Functional Index (TFI;
19
20 133 Meikle et al., 2012), and (5) be willing to complete questionnaires and a semi-structured
21
22 134 interview about their experiences of taking part in the trial. Patients were excluded if they (1)
23
24 135 had tinnitus with a medically treatable origin, (2) were unable to communicate in English, (3)
25
26 136 had comorbid conditions (e.g. dementia) which meant they were unable to give informed
27
28 137 consent, or (4) had participated in other tinnitus management research between consenting
29
30 138 and the start of the intervention. No exclusions were made because of previous experience
31
32 139 with psychological services or medications taken. All patients were enrolled at or before their
33
34 140 first visit to audiology with a primary complaint of tinnitus.
35
36
37
38
39
40
41

42 142 A member of the research team (JAT) was responsible for recruitment at Site 1. At Site 2 and
43
44 143 Site 3, the local PI was delegated responsibility for recruitment, with infrastructure support
45
46 144 provided by the National Institute for Health Research (NIHR) Clinical Research Network.
47
48 145 JAT regularly monitored recruitment at Sites 2 and 3 and maintained regular email contact
49
50 146 with the local PIs to offer support where recruitment rate was lower than required. However,
51
52 147 no additional support was requested during the trial.
53
54
55

56 148

58 149 **Intervention**

59
60

1
2
3 150 Psychologically informed treatment was delivered according to the treatment manual. This
4
5 151 involved an average of 2.75 sessions (range = 1-3) delivered one-to-one by an audiologist
6
7 152 who attended the training workshop.
8
9

10 153

11 154 **Control**

12 155 Patients allocated to the control condition received TAU from an audiologist not trained in
13
14 156 psychological therapy and who had not received training in the manualised intervention.
15
16 157 TAU typically involved management of hearing loss, education and advice, lasting an
17
18 158 average of 1.5 sessions (range = 1-2).
19
20
21
22
23

24 159

25 160 **Outcomes**

26 161 Feasibility of a powered RCT was predefined as (1) a recruitment efficiency of at least 10%
27
28 162 of those screened, (2) recruitment of at least 65% of the overall target sample size, (3)
29
30 163 retention of 80% of patients who were randomised, (4) completion of 80% for the primary
31
32 164 outcome questionnaires, and (5) patient and clinician compliance to the manualised tinnitus
33
34 165 counselling.
35
36
37
38
39

40 166

41
42 167 Six questionnaire were completed at each time point. The TFI is a measure of tinnitus
43
44 168 symptom severity over the last 2 weeks. It has 25 items (e.g. “Did you feel IN CONTROL in
45
46 169 regard to your tinnitus?”), each with a 10-point scale. Scores are summed and divided by 2.5
47
48 170 to give a total possible score between 0 and 100. The eight factor TFI has very high internal
49
50 171 consistency ($\alpha = 0.97$) (Meikle et al., 2012). It has excellent reliability, stability over time,
51
52 172 and sensitivity to individual differences in tinnitus severity, although the auditory subscale
53
54 173 (three items) may not contribute to the overall score (Fackrell et al., 2018).
55
56
57
58
59

60 174

1
2
3 175 The Tinnitus Cognitions Questionnaire (TCQ; Wilson & Henry, 1998) consists of a series of
4
5 176 statements preceded by the words “I think” or “I tell myself,” (e.g., I think “if only the noise
6
7 177 would go away”). The first 13 items refer to negative thoughts and the second 13 items refer
8
9
10 178 to positive thoughts. Responses are marked on a five-point Likert scale from “never” = 0, to
11
12 179 “very frequently” = 4. Positive items are reverse scored to give a total score from 0-104. The
13
14 180 TCQ has a reliable two-factor structure and high internal consistency ($\alpha = 0.90$) (Handscomb
15
16
17 181 et al., 2017).

18
19 182

20
21 183 The Clinical Outcomes in Routine Evaluation - Outcome Measure (CORE-OM; Barkham et
22
23 184 al., 2006) is a 34-item (four factor) measure of global distress. Respondents indicate how
24
25 185 much each item (e.g. “I have felt optimistic about my future”) has applied to them over the
26
27 186 past week, using a 5-point Likert scale from “not at all” to “most or all of the time”. The
28
29 187 CORE-OM includes both positive and negative items (positive items being reverse scored) to
30
31 188 give a total score from 0–136. Initial validation of this four factor questionnaire found it to
32
33 189 have high internal consistency ($\alpha = 0.94$) (Evans et al., 2002), although validation in a
34
35 190 tinnitus population found that a three factor structure provided a better fit to the data
36
37 191 (Handscomb et al., 2016).

38
39 192

40
41
42 193 The Health Utilities Index 15Q (HUI; Furlong et al., 2001) is a 15 item measure of health-
43
44 194 related quality of life. Items are multiple choice with 5-6 rank-ordered response options.
45
46 195 Decision tables of response combinations are used to determine the health-state level for each
47
48 196 domain within the questionnaire, and then using the tables and a scoring algorithm, utility
49
50 197 scores for all attributes of health and an overall health-related quality of life score is
51
52 198 determined. Overall scores range from -0.36 –1.00, where 0 = “death” and 1 = “perfect
53
54 199 health”. Estimates of the reliability of the HUI vary considerably (Busija et al., 2011).

1
2
3 200
4
5
6 201 The Working Alliance Inventory (WAI; Horvath & Greenberg, 1989) provides a measure of
7
8 202 the quality of alliance within counselling. It contains 36 items (e.g. “I was worried about the
9
10 203 outcome of the sessions”) scored on a Likert scale from 1 (Never) to 7 (Always). The WAI
11
12 204 contains both positive and negative items, with negative items being reversed scored, giving a
13
14 205 possible range of scores from 36 to 252. Reliability of the three WAI scale scores appear to
15
16 206 be high ($\alpha = 0.92, 0.92, \text{ and } 0.89$ respectively) although two subscales (“Tasks” and “Goals”)
17
18 207 were very highly correlated ($r = .92$).
19
20
21
22 208

23
24 209 The Client Service Receipt Inventory (CSRI; Beecham & Knapp, 2001) is an adaptable form
25
26 210 used to collect information on the whole range of services and supports study participants
27
28 211 may use. It contains items such as “Please list any use of inpatients hospital services over the
29
30 212 last three months”.

31
32
33 213
34
35 214 After randomisation, and in advance of their first audiology appointment, patients completed
36
37 215 the baseline study questionnaires. Questionnaires were completed again immediately at the
38
39 216 end of treatment and at follow-up or 6 months after the commencement of treatment
40
41 217 (excluding the CSRI which was only completed at follow-up). In practice, some 6-month
42
43 218 follow-up questionnaires were completed before the end of treatment. Patients received one
44
45 219 reminder (telephone or email) to complete the follow-up questionnaires if they had not been
46
47 220 returned within 2 weeks of their due date.
48
49
50

51 221

52 222 **Treatment fidelity**

53
54 223 Treatment fidelity required that treatment components were all consistency administered
55
56 224 according to the manual. Audiologists recorded administration of treatment components in a
57
58
59
60

1
2
3 225 case report form held for each patient, and took part in semi-structured interviews after the
4
5 226 last patient had completed their treatment. Interviews were used to determine which
6
7 227 components of the manualised care they thought worked well, why, and which components
8
9 228 were not useful. Patients involved in the intervention group also took part in semi-structured
10
11 229 interviews to discuss their experiences of the intervention. JAT or DMT conducted interviews
12
13 230 approximately 4 weeks after the last patient appointment. Clinician interviews were
14
15 231 conducted after discharge of their final patient. Interviews were audio-recorded, transcribed
16
17 232 verbatim and analysed using a thematic analysis approach (Braun & Clarke, 2006). DMT,
18
19 233 DMW, and two patient representative members of the lead centre's Patient and Public
20
21 234 Involvement (PPI) panel conducted analysis of the qualitative data.
22
23
24
25
26
27
28

236 **Deviations from protocol**

237 We had originally planned that public research partners trained in interview techniques would
238 conduct patient interviews. However, this ultimately proved unworkable due to the Sponsor's
239 stipulation that they would need formal registration as volunteers with the NHS Trust for this
240 activity. The process for this, involving application and interviews, was deemed too time
241 consuming to be accommodated within the study timeline. We had also originally planned to
242 discuss emerging themes in two focus groups with audiologists and patients, to ensure that
243 the themes and any identified barriers and facilitators to treatment implementation and
244 maintenance of self-management were accurately representative of patient and audiologist
245 experience. However, given the unanticipated length of the treatment process at sites, there
246 was insufficient time for this to be included within the funding period.

247

248 **Results**

249 **Demographic and clinical characteristics**

1
2
3 250 Nineteen patients were recruited to the trial and randomised to manualised care (n = 11) or
4
5 251 TAU (n = 8). Demographic characteristics are reported in Table 1. Mean baseline TFI score
6
7 252 was 67.08 (SD=23.644). Seven patients scored 25-50 on the TFI, scores interpreted as
8
9 253 tinnitus being a significant problem with a possible need for treatment (Henry et al., 2014).
10
11 254 Eleven patients scored above 50, interpreted as tinnitus severe enough to qualify for treatment
12
13 255 that is more intensive. Demographic data were missing for one patient.

INSERT TABLE 1 ABOUT HERE

259 **Feasibility outcomes**

260 Participant flow is presented in Figure 1, and feasibility outcomes are presented in Table 2.
261 Patients were screened from September 2016 to April 2017 (maximum six months from first
262 screen at each site). At Site 1, all 10 participants were recruited within a 3 month period; at
263 Site 2 three patients were recruited within a 3 month period, two of whom were recruited on
264 the same day); at Site 3 six patients were recruited within a 7 week period, five of whom
265 were recruited within the same week).
266
267 Six-month follow-up occurred from April to September 2017. Recruitment efficiency of
268 those screened surpassed the feasibility target at Site 1 where 10 eligible patients were
269 enrolled from just 16 patients screened (63%), while the target was one enrolment for every
270 10 patients screened (10%). Recruitment efficiency was also met at Site 2, where 24 patients
271 were screened and three patients were recruited (13%). This difference in recruitment
272 efficiency is in part a consequence of different patient pathways; at Site 1 all patients were
273 referred by their GP to ENT, and from ENT onto audiology. At Site 2 some patients were
274 referred directly to audiology by their GP. Indeed 10 of the 24 patients screened at Site 2

1
2
3 275 were assessed by the audiologist as requiring referral to ENT or psychiatry and therefore not
4
5 276 eligible for the trial. Also at Site 2, one recruited patient failed to attend any further
6
7
8 277 appointments, and three patients screened as eligible declined to participate due to the time
9
10 278 commitments involved and geographical distance between home and the audiology service.
11
12 279 Site 3 did not return their screening records so we were unable to assess feasibility.
13

14 280

15
16
17 281 ***INSERT TABLE 2 ABOUT HERE***
18

19 282

20
21 283 Nineteen patients were recruited and consented to take part in the study; representing a total
22
23 284 recruitment of 63% (feasibility target was 65%). Site 1 surpassed the target for feasibility
24
25 285 with 100% recruitment. Site 2 recruited three patients (30%) and Site 3 recruited six (60%).
26
27
28 286

29
30 287 Nine out of 19 patients were retained in the trial until the end of treatment, representing a
31
32 288 retention rate of 47% (feasibility criterion was 80%). Reasons for discontinuation included
33
34 289 spontaneous remission (n = 1), identification of Alzheimer's disease (n = 1), trial site error in
35
36 290 allocating patients to treatment arms (n = 1), loss to follow-up (n = 2), declined to participate
37
38 291 further (n = 1), or commenced other treatment (n = 3).
39

40 292

41 293 **Effectiveness outcomes**

42 294

43 295 Completeness of questionnaire data is given in Table 2, and descriptive statistics are
44
45 296 presented in Table 3. TFI, TCQ, TCQ negative thoughts subscale, and CORE-OM scores
46
47 297 decreased between baseline and the end of treatment. TFI scores continued to decrease
48
49 298 between the end of treatment and 6-month-follow-up, whereas TCQ and CORE-OM scores
50
51 299 were maintained between the end of treatment and 6-month follow-up. TFI emotional distress
52
53 300 subscale scores increased between baseline and the end of treatment, but decreased below
54
55 301 baseline by 6-month-follow up. Patients and audiologists' scores on the WAI task, bond, and
56
57
58
59
60

1
2
3 302 goal subscales all increased between baseline and end of treatment. No adverse events or
4
5 303 adverse reactions were recorded during the trial.
6
7
8 304

9
10 305 ***INSERT TABLE 3 ABOUT HERE***
11
12 306

13 14 307 **Treatment fidelity and experience**

15
16 308 Six themes emerged from thematic analysis of interview transcripts: (1) acceptability of and
17
18 309 fidelity to treatment components, (2) factors affecting fidelity, (3) refining treatment
19
20 310 components, (4) factors affecting feasibility of wider implementation of treatment, (5)
21
22 311 training and supervision, and (6) measurement of tinnitus outcomes.
23
24 312

25
26 313 (1) Acceptability of and fidelity to treatment components.
27
28
29 314

30 314 Patients and audiologists use, acceptance of, and fidelity to the treatment components varied.
31
32 315

33 315 All audiologists reported that they actively promoted physical activity, and patients reported
34
35 316 that they engaged in physical activity during the trial, despite it temporarily increasing
36
37 317 awareness of tinnitus. Other components were not used consistently, e.g. one audiologist and
38
39 318 one patient (from different sites) stated that they did not formally set any goals for treatment,
40
41 319 thereby deviating from the treatment protocol:
42
43 320

44 320 *“We didn’t set any formal goals, it was just a case of, I would go away and see...*

45 321 *whether it’s got any worse or whether it got any better and in actual fact it’s stayed*

46 322 *about the same.” (Patient 2).*
47
48
49 323

50 323 Another audiologist explained that goal setting can be challenging without first engaging in
51
52 324 tinnitus education to explain to the patient that they cannot cure their tinnitus:
53
54
55
56
57
58
59
60

1
2
3 325 “... I find the preliminary bit of goal setting a bit difficult because you’ve got to start
4
5 326 by saying, ‘we can’t cure your tinnitus, so with that in your mind, what would you like
6
7 327 to do?’” (Audiologist 3).
8
9

10 328 All patients reported being reassured by receiving information about the causes, maintenance,
11
12 329 and change in tinnitus over time, and for some patients, education was considered sufficient
13
14 330 intervention. For many patients the cognitive behavioural model of tinnitus reflected their
15
16 331 personal experiences of tinnitus. Patients and audiologists also commented that the model
17
18 332 was understandable:
19
20

21 333 *I think [the cognitive behavioural model is] quite a nice one because it’s quite logical,*
22
23 334 *the language that it uses is fairly easy, is nothing too sort of technical or too medical*
24
25 335 *and you can [work] through [the manual] in a logical way.” (Audiologist 2)*
26
27

28 336 Relaxation was acceptable to audiologists although it was used sparingly and briefly in and
29
30 337 outside of appointments. Patients mostly reported using relaxation to improve sleep. Patients
31
32 338 and audiologists also highly valued the inclusion of education about sleep cycles in treatment.
33
34 339 Patients in the trial did not use sleep diaries, sleep monitoring devices were favoured,
35
36 340 although the principle of monitoring sleep to identify poor sleeping habits was maintained:
37
38

39 341 *“No, I’ve been using [a fitness watch and not the sleep diary] because that records in*
40
41 342 *quite reasonable detail the amount of sleep you’ve had.” (Patient 1)*
42
43

44 343 Cognitive techniques received mixed reviews. Some patients expressed an understanding of
45
46 344 avoidance as a mechanism of tinnitus-related distress and recognised when they were
47
48 345 engaging in avoidance behaviours:
49
50

51 346 *“I avoided noisy environments. So, like if friends invited me round for a party, I*
52
53 347 *always used to make excuses not to go...” (Patient 3)*
54
55

56 348 Audiologists also demonstrated an understanding of safety behaviours such as avoidance.
57
58 349 However, at least one felt unable to recognise avoidance consistently in various contexts:
59
60

1
2
3 350 *“Safety [avoidance] behaviours...seems very obvious when you read the words.... But*
4
5 351 *then actually when the patient starts talking about the things that they do and their*
6
7 352 *feelings and their attitudes and how they deal with things you don’t necessarily think,*
8
9
10 353 *‘that’s a safety behaviour’.” (Audiologist 1)*
11

12 354 At least one audiologist found thought challenging prompts included in the treatment manual
13
14 355 useful, but fidelity to the thought-challenging component varied, often limited to identifying
15
16 356 negative thoughts without challenging them:

17
18
19 357 *“I didn’t use the thought record sheets. I used the unhelpful thinking styles [material],*
20
21 358 *and patients do find this one quite useful and quite often they’ll point out, ‘yeah,*
22
23 359 *that’s me’, and so that helps us to address some of these thoughts.” (Audiologist 3)*
24
25

26 360 When thought challenging was used, audiologists either considered the technique ineffective,
27
28 361 or believed the benefit would only be short term:

29
30 362 *“Most of the time [patients] don’t [think of a more helpful realistic thought]. And I*
31
32 363 *don’t know whether that’s because I’m not enabled enough or whether they just can’t*
33
34 364 *do it.” (Audiologist 1)*
35
36

37 365 The attention, monitoring and acceptance component of the manual was used in treatment but
38
39 366 not consistently or as instructed in the manual. One audiologist introduced the concept of
40
41 367 mindfulness, and two used metaphors when they thought it would be acceptable to patients.
42
43 368 However, one patient reported their audiologist used metaphors as an imagination exercise
44
45 369 rather than as an (intended) defusion technique:

46
47
48 370 *“We didn’t go through too many metaphors, obviously the metaphors of aligning the*
49
50 371 *sounds of your tinnitus to natural sounds. We didn’t talk about particular river*
51
52 372 *banks.” (Patient 1)*
53
54
55
56
57
58
59
60

1
2
3 373 Finally, relapse prevention was not addressed according to the manual. Patients remembered
4
5 374 being advised to return if their symptoms worsened or if self-management using the
6
7
8 375 techniques learned during the treatment were not effective:

9
10 376 *“I don’t think [the audiologist] did [share the relapse prevention handout] actually,*
11
12 377 *no because I don’t think we got on to that point actually.” (Patient 1)*

13
14 378

15
16
17 379 (2) Factors affecting fidelity

18
19 380 Audiologists reported a lack of confidence in implementing treatment components including
20
21 381 relaxation, acceptance-based components, and goal setting. One suggested that rigid use of
22
23 382 the manual would impair the development of the therapeutic relationship, particularly for less
24
25 383 experienced audiologists, and in contrast, another felt that the manual would help less
26
27 384 experienced audiologists by providing a structure to follow. For one audiologist, confidence
28
29 385 reportedly augmented with increasing experience during the trial:

30
31
32
33 386 *“You’re always a little bit nervous to start with. However, I found that after the first*
34
35 387 *few appointments it’s just flown. You develop your own pattern in appointments and I*
36
37 388 *guess I developed a pattern very, very quickly and that’s because it was very intense*
38
39 389 *training...” (Audiologist 3)*

40
41
42 390 Patients sometimes resisted the use of treatment components such as thought challenging or
43
44 391 mindfulness. Audiologists stated their patients would report not having enough time to
45
46 392 engage with the treatment outside of appointments, or just believed that the treatment would
47
48 393 be unsuccessful. Audiologists also considered some treatment components were within the
49
50 394 scope of practice of psychologists or hearing therapists, but not theirs:

51
52
53
54 395 *“To me [thought challenging] is a logical skill and I don’t know that that’s my*
55
56 396 *leaning at all. To say to somebody, ‘well that thought you are having there is very*
57
58 397 *unhelpful’ ...if you’re a psychologist you could do that. But I can’t.” (Audiologist 1)*

1
2
3 3984
5 399 (3) Refining treatment components6
7 400 Patients and audiologists recommended changes to the manual. These included expanding the
8
9 401 physical exercise component to include lifestyle advice on diet and alcohol.10
11 402 *“That’s something that we do anyway so within the tinnitus therapy process we*
12
13 403 *always talk about lifestyle choices. So, physical exercise comes into that but we also*
14
15 404 *talk about things like diet, we might also talk about you know where patients are*
16
17 405 *maybe drinking excessively.” (Audiologist 3)*18
19 406 *“If they’ve taken up hobbies that have enabled them to be more distracted, sort of*
20
21 407 *reinforcing those things and said, ‘these are the things that you know are going to*
22
23 408 *enable you in the long term to sort of ignore your tinnitus and live with it happily’.”*
24
25 409 *(Audiologist 2)*26
27 410 One audiologist found that some patients’ lack of motivation was a barrier to their
28
29 411 engagement in the treatment and that a technique to improve motivation would be useful.30
31 412 *“It’s like how can we break this down...what happens when you can’t motivate a*
32
33 413 *patient... how do you tackle somebody who is clearly giving you excuses...? Cause*
34
35 414 *there’s a harsh way which is, ‘look, you’re just giving lots of excuses.’ But that’s not*
36
37 415 *the way to do it. That doesn’t help anybody. But then is it up to us to go into maybe*
38
39 416 *the deeper reasons why they’re doing that, is it a confidence issue [for example], and*
40
41 417 *it’s that thing that’s stopping that patient from getting better.” (Audiologist 3)*42
43 418 (4) Factors affecting feasibility of wider implementation of treatment44
45 419 Audiologists unanimously agreed the treatment did not lengthen the amount of time spent
46
47 420 with patients throughout their care. However, participation in the intervention arm of the trial
48
49 421 affected the usual appointment structure. For example, the audiologists delayed hearing aid
50
51 422 fitting to allow time to gather information about underlying mental health problems first.
52
53
54
55
56
57
58
59
60

1
2
3 423 Audiologists also thought that reducing the time between appointments could increase
4
5 424 treatment benefit:

6
7
8 425 “ [reducing] follow-up [from] about 12 .. to...6 weeks after the initial appointment...
9
10 426 works because patients either take on board everything you say or they struggle with
11
12 427 it and if you’ve kind of let them go for three months you’re almost back to square one
13
14 428 sometimes.” (Audiologist 1)

15
16
17 429 However, concern was expressed that such changes to appointment structure might not be
18
19 430 feasible in audiology services where resources are limited. Continuity of care, with patients
20
21 431 seeing the same audiologist throughout their care was also considered beneficial:

22
23
24 432 “.. some patients even though they are hearing aid patients, probably would benefit
25
26 433 from being fitted by the tinnitus audiologist rather than an [other] audiologist
27
28 434 because some of the reasoning behind why we’re fitting the hearing aid has to be
29
30 435 related to the tinnitus. And perhaps that was lost ...” (Audiologist 2)

31
32
33 436

34
35 437 (5) Training and supervision

36
37 438 Audiologists were introduced to the manual across 2 days of training. Although audiologists
38
39 439 valued the small group setting, the content of the 2 days was considered overwhelming.

40
41 440 Audiologists involved in the trial suggested that it might not be feasible to implement this
42
43 441 format outside of the trial for routine clinical practice:

44
45
46 442 “It was excellent, one-to-one with a group of experts, what else could you ask for?
47
48 443 ...Feasibility-wise, would that work in practice? Probably not.” (Audiologist 3)

49
50
51 444 Some audiologists recommended role-play to improve the training to provide practice and
52
53 445 feedback on techniques in a range of scenarios in order to help audiologists to understand
54
55 446 how components of the manual would work in practice. All audiologists felt that formal

1
2
3 447 supervision arrangement would be helpful to check adherence to the treatment manual.
4

5 448 However, audiologists also noted the lack of supervision within audiology:
6

7
8 449 *“In adult audiology, we work in a silo... we don’t have anyone else except our*
9
10 450 *colleagues to turn to, we don’t have any formal supervision like you would if you were*
11
12 451 *a therapist.” (Audiologist 3)*
13

14 452 The potential for the treatment manual to be used as a training tool for inexperienced
15
16 453 audiologists was raised repeatedly during interviews:
17

18
19 454 *“I found [the manual] quite useful in terms of training somebody new to sort of say,*
20
21 455 *‘do you want to delve a bit deeper, is there something in these questions that perhaps*
22
23 456 *is relevant for the patient you’ve got sat in front of you?” (Audiologist 2)*
24
25

26 457

27
28 458 (6) Measurement of tinnitus outcomes
29

30 459 Patients and audiologists recognised that all the domains measured by the TFI and TCQ could
31
32 460 be relevant to different patients, and no additional domains were identified as relevant that
33
34 461 were not measured in the trial. The TFI was favoured as an assessment tool by patients and
35
36 462 audiologists because of its broad coverage across tinnitus problem domains to enable
37
38 463 identification of relevant treatment options. However, one audiologist highlighted that some
39
40 464 patients conflate hearing loss and tinnitus when completing the TFI, which may limit its
41
42 465 ability to distinguish between tinnitus-related and hearing-related distress. Audiologists were
43
44 466 less familiar with the TCQ, although one appreciated it as a means to encourage patients to
45
46 467 recognise and talk about their negative thoughts about tinnitus:
47
48
49

50
51 468 *“Sometimes patients are quite reluctant to give [negative thoughts], some patients*
52
53 469 *don’t like feelings, but to get them to write it down and to score it, you get a bit more*
54
55 470 *of an overview of about where they are and how severe really the tinnitus is and how*
56
57 471 *much it is affecting them psychologically. So that again I’ve not used that one [TCQ]*
58
59
60

1
2
3 472 *routinely but I do think that one is one that I would probably use for those patients*
4
5 473 *where I'm perhaps struggling to see how much is affecting them psychologically."*
6
7
8 474 *(Audiologist 2)*
9

10 475 Patients also welcomed the use of tinnitus questionnaires to monitor their improvement
11
12 476 during treatment:

13
14 477 *"It makes you start to realise how well you're doing and it gives you a chance to*
15
16 478 *measure that...how bad it is or how you're managing really well."* (Patient 2)
17
18

19 479 Patients and audiologists had different views on the difficulty of completing questionnaires.

20
21 480 Whereas audiologists perceived questionnaires to be accessible, patients thought that support
22
23 481 should be offered to complete any questionnaires:

24
25 482 *"When you give a questionnaire like this and just give it to somebody – and I was put*
26
27 483 *in another room to do it – I think there's an assumption made that everyone can do*
28
29 484 *that task."* (Patient 2)
30
31
32

33 485

34 35 486 **Discussion**

36
37 487 This study was the first to develop and assess feasibility of trialling an audiologist-delivered
38
39 488 low intensity psychological intervention for tinnitus. Ultimately, we aimed to provide an
40
41 489 evidenced-based, costed, manualised approach to tinnitus care that is attractive to
42
43 490 commissioners and represents a flexible and accessible tinnitus treatment. The feasibility trial
44
45 491 reported here determined that a manualised psychologically informed treatment was
46
47 492 acceptable to patients and audiologists, but that it is not yet feasible to test in a multi-site
48
49 493 effectiveness trial. Recruitment reached only 19 patients (63%) after 6 months, just short of
50
51 494 the 65% target for feasibility, while average retention for the duration of the trial reached
52
53 495 only nine patients (47%), very short of the 80% target for feasibility. Patient recruitment is
54
55 496 acknowledged to be one of the most difficult and least predictable elements of a clinical trial.
56
57
58
59
60

1
2
3 497 (Allen et al., 1998; Thoma et al., 2010; Sanchez et al., 2018). Here, performance varied
4
5 498 across the three sites. The best in terms of recruitment efficiency and recruitment rate was
6
7 499 Site 1, an audiology service based in a large teaching hospital where staff are supported to be
8
9
10 500 research active. Having a large pool of potentially eligible patients to draw on, as well as
11
12 501 engaging with audiologists who have previous experience in participating in RCTs, are
13
14 502 known factors that can help to achieve study targets for hearing trials (Sanchez et al., 2018).
15
16 503 In addition, a member of the research team was responsible for recruitment at Site 1, and did
17
18 504 not have to contend with the same clinic demands as PIs at the other sites. That said, the
19
20 505 pattern of recruitment would suggest all could have reached feasibility. Site 3 in particular
21
22 506 recruited five patients (50% of target) within a single week, suggesting competing demands
23
24 507 and/or a lack of engagement with the research, rather than low patient numbers, were barriers
25
26 508 to recruitment at that site. In contrast, Site 1 performed poorest in terms of patient retention
27
28 509 indicating that even experienced participating sites need a risk mitigation plan and regular
29
30 510 trial monitoring. We would concur with the recommendations suggested by Sanchez et al.
31
32 511 (2018) that a future RCT needs to ensure that it has sufficient resource to support a carefully
33
34 512 specified plan to promote recruitment and retention of tinnitus patients. Furthermore, based
35
36 513 on current findings, we would suggest that treatment fidelity could be improved and more
37
38 514 accurately monitored by (1) including an audiologist familiarisation phase of treatment
39
40 515 implementation before including patients in analyses, and (2) including direct in-session
41
42 516 observation of a random selection of treatment sessions using standardised fidelity evaluation
43
44 517 forms, based on the treatment manual.
45
46
47
48
49
50

51 518
52
53 519 From the Delphi survey (Thompson et al., 2018) we know that psychoeducation and common
54
55 520 therapeutic skills are considered more important than specific CBT techniques in
56
57 521 psychological tinnitus treatment. Patients and audiologists considered it essential to include
58
59
60

1
2
3 522 psychoeducation and common therapeutic skills (aimed at informing the patient and
4
5 523 conveying empathy) in psychological tinnitus treatment. Giving patients information about
6
7 524 common cognitive distortions was considered essential, but cognitive restructuring was not.
8
9
10 525 This pattern suggests that patients and audiologists understood the contribution of
11
12 526 maladaptive behaviours and negative thoughts to bothersome tinnitus, but did not think that
13
14 527 the audiologist's role should or could extend to managing patients' use of specific cognitive
15
16 528 behavioural techniques. This issue was further highlighted in the current trial. Interviews
17
18 529 revealed audiologists chose not to use certain psychological treatment components from the
19
20 530 manual because (1) they lacked confidence in using them as training was brief and
21
22 531 insufficient for them to learn how to implement them safely and effectively, (2) they thought
23
24 532 patients do not want to record, monitor, and challenge specific negative thoughts and
25
26 533 behaviours, and (3) they believed certain components would be ineffective. More work is
27
28 534 therefore required to consider what audiologists can and want to deliver either within their
29
30 535 current or a revised clinic and appointment structure, and what training and supervision
31
32 536 arrangements need to be in place for these skills to be developed, used, and maintained
33
34 537 throughout a clinical trial. Beyond feasibility and evaluation of effectiveness, it will also be
35
36 538 essential to explore how the intervention can be implemented into routine clinical practice,
37
38 539 which will involve further challenges such as organisational development, workplace cultures
39
40 540 and individual barriers (De Silva, 2015).

41
42 541
43
44 542 Similar issues are being faced in other areas. For example, there is emerging evidence that
45
46 543 CBT-enhanced voice therapy for functional dysphonia leads to greater improvement in
47
48 544 general well-being and distress (Miller, Deary, & Patterson, 2014), but as with the current
49
50 545 study there are open questions about how clinicians should be trained and supervised and
51
52 546 how cost-effective this approach may be. There are examples in other fields of how training
53
54
55
56
57
58
59
60

1
2
3 547 might be achieved on a large scale. Richmond et al. (2016) evaluated feasibility of an online
4
5 548 programme to train physiotherapists in the use of cognitive behavioural approaches to the
6
7 549 management of non-specific low back pain. They found an internet-based approach to
8
9 550 training to be equivalent to face-to-face group training in terms of retention of theoretical and
10
11 551 procedural knowledge. However, clinicians who received the face-to-face training showed
12
13 552 greater self-efficacy in delivering the assessment component of the therapy, were more
14
15 553 satisfied with their training, and were more 'psychosocially' rather than 'biomedically'
16
17 554 orientated after training, and by implication were more aligned with a cognitive behavioural
18
19 555 approach. Regardless, uptake of the treatment approach after training was similar across both
20
21 556 groups (about one third). Their conclusion, that there is a need to develop strategies for
22
23 557 training and support to deliver treatments that use cognitive behavioural approaches, read
24
25 558 relevant to all allied health professionals at this time. In the context of the current study,
26
27 559 issues such as the acceptability and preference for different training formats will need to be
28
29 560 explored.
30
31
32
33
34
35
36

37 561
38 562 Certain revisions to the TinMan study manual and training require consideration before it can
39
40 563 be subjected to further feasibility testing. These include additional information about tinnitus
41
42 564 and psychoeducation, including information about negative thought patterns and avoidant
43
44 565 behaviours. An appreciation of patient preference and need with respect to psychological
45
46 566 treatment components was also apparent in the current study. Specific cognitive behavioral
47
48 567 techniques tend to purposefully engage patients in initially unwanted, though temporary,
49
50 568 thoughts or emotional states. It is of importance to train audiologists in how to deal with these
51
52 569 challenges and ultimately make use of the patient-states resulting from these approaches. The
53
54 570 natural resistance and transferal of distress in both patients and audiologists when using these
55
56
57
58
59
60

1
2
3 571 techniques needs to be adequately covered in training that balances informed patient choice
4
5 572 and need.
6
7

8 573
9 574 **Conclusion**

10
11 575 What emerged most strongly from this study is that an audiologist-delivered low-intensity
12
13 576 psychological intervention is an acceptable approach to tinnitus management, but even very
14
15 577 experienced audiologists require more extensive training to ‘upskill’ in the use of
16
17 578 psychological treatment components. Audiologists involved in delivering the psychological
18
19 579 treatment reported that the amount of training was insufficient and lacked role-play and
20
21 580 feedback from a supervisor to increase understanding of how to deliver the treatment
22
23 581 effectively. This needs to be addressed before further testing. One potentially cost-effective
24
25 582 means of training audiologists may be to develop reusable learning objects, e.g. including
26
27 583 video recordings of role-play scenarios where an audiologist is using a set of psychological
28
29 584 techniques from the manual. Once training is addressed, the treatment may progress to further
30
31 585 feasibility testing. There has been recent discussion in the UK audiology community about
32
33 586 some form of compulsory continual professional development or qualification in tinnitus care
34
35 587 for practicing audiologists. The manual developed here, and the training resources that will
36
37 588 support its use, could potentially meet this perceived need.

Supplemental Information 1. OVERVIEW OF MANUAL

The materials in this manual are for delivery to NHS patients with intrusive tinnitus by an audiologist. It requires use of core counselling skills within the context of relationship building between audiologist and patient working in partnership with one another in a therapeutic alliance. Beginning with assessment, using the Relational Skills Model (more detail in [Appendices, Section 9](#)), the audiologist works in partnership with the patient through the following process:

| PHASES OF RELATIONSHIP DEVELOPMENT | PROCESS | SKILLS |
|---|---|---|
| Setting up the relationship | Contacting/meeting the patient Getting to know the patient Communicating with & contracting with the patient | Initial core skills: Attending skills Active listening skills & contracting skills |
| Developing the relationship | Developing the relationship Problem identification & assessment | Additional core skills: Presence & communication of the core conditions Paraphrasing Summarising Identifying & reflecting feelings, content & meaning Asking questions |
| Working with the relationship | Challenging & creating new meaning, different possibilities & perspectives | Enhanced skills: The skill of challenging – Confronting Use of self-disclosure, immediacy & silence Clarifying Reassessing Probing Giving feedback & sharing information |
| The established relationship | Clarifying & focusing on likely changes Working collaboratively to make plans, set goals, & consider & evaluate possible strategies & directions | Intuitive & learned skills: Deeper empathy Focusing Use of metaphor & hunches Drawing together themes Clarifying & identifying goals Action planning |
| Maintaining and ending the relationship | Implementing & maintaining change Supporting self-management strategies | Embedding skills: Encouragement, support & affirmations Review, monitor, evaluate & facilitate ending Signposting/referring on |

Midwinter R, Dixon J (2015) *Embedding Counselling and Communication Skills. A Relational Skills Model*. Routledge, Hove: p.3

1
2
3
4 The process and skills used (more detail below) allow for the British Society of Audiology
5 (BSA) Practice Guidance: Common Principles of Rehabilitation for Adults in Audiology
6 Services to be fulfilled. These are:
7

- 8 • Identifying individual needs
- 9 • Setting joint goals
- 10 • Making shared informed decisions
- 11 • Supporting self-management
- 12
- 13
- 14

15 **CORE COUNSELLING SKILLS**

16 **Attending and listening**

- 17 • Active listening
- 18 • Listening with purpose and responding in such a way that patients are aware they
- 19 have been heard and understood
- 20
- 21
- 22
- 23

24 **Reflective skills**

- 25 • *Restating* what you believe to be a significant word or phrase the patient has used
- 26 • *Paraphrasing* involves conveying the patient's core messages (facts and feelings) in
- 27 your own words
- 28 • *Summarising* is offering the patient a précis of the information they have given you –
- 29 not as a list of details and facts but as an organised overview of important themes or
- 30 cluster of concerns
- 31
- 32

33 **Reflective skills:**

- 34 • Capture what a patient is telling you and repeat the message in your own words
- 35 • Are valuable for 'tracking' patients, since they impose minimal direction from the
- 36 practitioner
- 37 • Enable the practitioner to communicate the core values, to clarify and to
- 38 acknowledge the patient's experiences
- 39 • Build relationships that are supportive and challenging
- 40 • Are ideal information-gathering skills
- 41
- 42
- 43
- 44

45 **Probing skills**

- 46 • *Questioning* to facilitate exploration
- 47 • *Making statements* is a gentle form of probing. For example, instead of asking a
- 48 patient, "*What did she do to upset you?*", you might say, "*I'm not sure what she did to*
- 49 *upset you*". Statements tend to be less intrusive and controlling than questions
- 50
- 51

52 **Probing skills:**

- 53 • Tend to focus on what the practitioner wants to know and not necessarily on what the
- 54 patient wants to tell
- 55 • Lead or direct patients
- 56 • Help to obtain information from the patient
- 57 • Influence direction of the exploration
- 58 • Increase practitioner control over process and content
- 59
- 60

- Should be used with care because of the above, especially in the early stages

STRUCTURE OF MANUAL

As shown in the [Table of Contents \(page 2\)](#), the process of treatment comprises six broad sections:

- Patient assessment
- Rationale for psychologically informed treatment
- Goal setting and treatment planning
- Patient education
- Patient management/self-management (with eight sub sections)
- Relapse prevention

At the end of [Patient Assessment \(Section 2\)](#) there are recommendations about which elements of [Patient Education \(Section 5\)](#) and [Patient Management/Self-Management \(Section 6\)](#) to focus on dependent on individual needs. However, it is recommended that [Rapid Relaxation \(Section 6.2\)](#) should be a core (non-optional) element of Patient Management/Self-Management.

If it is agreed that the patient would benefit from psychologically informed treatment, it is important to discuss the [Rationale for Psychologically informed Treatment \(Section 3\)](#) with them prior to [Goal Setting and Treatment Planning \(Section 4\)](#). Having worked through relevant elements of [Sections 5 and 6](#), conclude the treatment with [Relapse Prevention \(Section 7\)](#).

The [Bibliography \(Section 8\)](#) contains references related to the intervention, training resources and further reading. The [Appendices \(Section 9\)](#) contain materials used to train audiologists in the use of the manual.

TOOLKIT OF RESOURCES

The manual is supported by a separate toolkit booklet (and electronic files) comprising resources to aid the delivery of tinnitus management and enable learning by the patient as s/he works through the process in partnership with the audiologist. Guidance for what resources to use and when to use them is highlighted in **red** throughout the manual. You are expected to print/photocopy specific resources from the toolkit as required for each patient.
