13 The synthesis, spectroscopic characterization, single-crystal X-ray diffraction (SCXD)
14 analysis, and Density Functional Theory (DFT) and time-dependent DFT (TD-DFT) studies of
15 the coordination compound of *cis*-dichloroplatinum(II) with a sterically hindered N₄-donor
16 ligand, 3,3'-bis(NH-benzimidazol-2-yl)-2,2'-bipyridine (L), [Pt(L)Cl₂].DMSO (**1**) (DMSO =
17 dimethylsulphoxide) are reported. The Pt(II) ion adopts a slightly distorted square-planar
18 geometry in which L coordinates in a bidentate fashion to the metal center via unprecedented
19 way through N atom of benzimidazole (bim) and N atom of pyridine (py) to form a seven-
20 membered ring. The molecular units in the lattice are held together in a head to tail fashion as
21 a dimer through intermolecular hydrogen bonding between the uncoordinated bim and py rings
22 in the molecule through N–H···N hydrogen bonds with the R_2^2 (14) graph-set motif. The lattice
23 DMSO solvent molecule significantly stabilizes the structure through N–H···O hydrogen bond
24 with the coordinated bim in the structure. Hirshfeld surface analysis also confirmed the
25 hydrogen bond interactions in the crystal. DFT and TD-DFT results show that optimized
26 geometry and UV-vis absorption spectra are consistent with the experimental results. Natural

27 bond orbital (NBO) properties show that the hydrogen bond stability between two monomers
28 is attributed to large stabilization energy values.

29 **KEYWORDS** Platinum, bipyridine, benzimidazole, X-ray, H-bond, DFT

30 1 INTRODUCTION

31 The coordination compounds of sterically hindered ligand, 3,3'-bis(NH-benzimidazol-2-yl)-
32 2,2'-bipyridine, exhibit luminescence properties at room temperature [1–4]. The ligand
33 incorporating pyridine and benzimidazole moieties functions as a hydrogen donor and acceptor.
34 Therefore, it is of interest in supramolecular chemistry due to non-covalent interactions that
35 play a significant role in the formation and stabilization of the structures [4]. The previous
36 studies on the transition metal complexes of this ligand reveal that the ligand coordinates to the
37 metal center solely through the benzimidazole N atoms in a bidentate fashion [1–4]. The ligand
38 forms 1:1 complexes with Co(II) and Cu(II), and 1:2 complex with Zn(II) ion [2]. In all
39 complexes, the metal center preferentially adopts a distorted tetrahedral geometry. The dihedral
40 angles between the pyridine and benzimidazole rings depend on the hydrogen bonding ability
41 of the ligand (intramolecular N–H···N bonds) [4]. The binding of the ligand to the metal center
42 usually increases the intensity of the emission maxima and also causes a blue shift due to
43 coordination which influences the conjugation in the molecule [1]. These spectral changes
44 brought by the solvent molecules are of significance to the development of chemical sensors
45 [5]. These compounds show luminescence changes in the visible spectral region upon
46 coordination to the metal ion and also upon changing the pH of the solution [2]. The metal
47 center in the coordination compounds of the ligand with Cu(II), Co(II), Zn(II), Cu(I), and Ag(I)
48 ions shows a preference for a distorted tetrahedral geometry [2]. To the best of our knowledge,
49 this is the first study on the coordination chemistry of the ligand with a d^8 platinum(II) ion. It
50 is well known that the diamine-platinum(II) complexes show intriguing spectroscopic
51 properties due to Pt···Pt stacking interactions in the solid-state lattice [6]. Motivated by this
52 synergy and its potential supramolecular properties, here we report the synthesis, single-crystal
53 X-ray analysis, spectroscopic properties, Hirshfeld Surface (HS) analysis, DFT studies, and

electronic properties of the platinum(II) complex with this very interesting sterically
encumbered ligand having hydrogen donor and acceptor ability.

2 EXPERIMENTAL

2.1 Materials and instrumentation

All analytical grade reagents were obtained from commercial sources and used without further purification unless otherwise stated. Infrared spectra were recorded on a Perkin-Elmer Spectrum 100 FT-IR spectrophotometer with an attenuated total reflection (ATR) accessory featuring a zinc selenide (ZnSe) crystal at room temperature. Electronic absorption spectra were measured on a CARY 100 Bio UV-Visible spectrophotometer in DMSO solution at room temperature. The ¹H NMR spectra were obtained at room temperature in DMSO-*d*₆ using an Agilent 300 MHz Premium Compact NMR spectrometer. Chemical shifts are given in parts per million with reference to TMS. MS analyses were performed by using Agilent 6530 Accurate-Mass Quadrupole Time-of-Flight LC/MS. The ligand, 3,3'-bis(NH-benzimidazole)-2,2'-bipyridine (L) was prepared as previously reported by us [2]. Characterization data for L are identical to those of the reported data [2].

2.1 Synthesis of dichloro-(3,3'-bis(NH-benzimidazol-2-yl)-2,2'-bipyridine)platinum(II) dimethylsulphoxide (1)

The preparation of [Pt(L)Cl₂](CH₃)₂SO (1) was adapted from the literature method [7]. To the solution of K₂PtCl₄ (0.41 g; 1.0 mmol) in hot water (50 cm³) was added L (0.43g; 1.10 mmol) in HCl (3M, 15 mL) at rt, The reaction mixture was set to reflux for 12 h with vigorous stirring. The precipitate as yellow solid was filtered and washed with water and ethanol. The single crystals of good quality for X-ray diffraction analysis were obtained by slow diffusion of diethyl ether into a concentrated DMSO solution at r.t. FT-IR (KBr, ν cm⁻¹); 3576 (m, ν OH), 3393 (w,

77 ν N-H), 3156 (m, ν Ar-H), 3065 (ν Ar-H), 1616 (w, δ OH), 1590 (w, δ N-H), 1561 (s, py and bim

80 H), 707 (vs, δ Ar-H). LC-ESI-MS m/z: 647.1. 1 H NMR (300 MHz, DMSO- d_6): δ 8.5 (d, J = 7.8
81 Hz, 2H, 6,6'-bpy), 8.4 (d, J = 4.8 Hz, 2H, 4,4'-bpy), 8.1 (d, J = 7.9 Hz, 2H, 5,5'-bpy), 7.8 (d, J
82 = 7.8 Hz, 2H, benzene ring), 7.7–7.6 (m, 6H, benzene ring).

83 2.2 Crystal structure determination

84 Data collections were performed on a Bruker-Nonius KappaCCD diffractometer equipped with
85 a rotating anode to produce graphite-monochromatic Mo- K_α radiation. The structure was solved
86 by direct methods using SHELXT [8] and refined by full-matrix least-squares methods on F^2
87 using SHELXL [8] from within the Olex2 [9] suite of software. The H atoms of C atoms were
88 refined using the riding model. Molecular diagrams were created using Olex2 and Mercury
89 [10]. Details of data collections and crystal structure determinations are gathered in Table 1.
90 The selected bond lengths and angles for **1** are listed in Table S1 and S2, respectively. The
91 hydrogen-bonds geometries are summarized in Table 2. Crystallographic data for the structures
92 reported in this paper have been deposited in the Cambridge Crystallographic Data Center with
93 CCDC deposition number 1010892 and RefCode XONLOD for **1**.

94 “Table 1”
95

96 Hirshfeld Surface (HS) analysis [11] for the crystal structure of **1** was carried out with Crystal
97 Explorer version3.1 [12] to clarify the formation of the dimer structure by H-bond interaction.

99 2.3. Computational details

100 The geometry optimizations were performed with Gaussian09 [13] using Density
101 functional theory (DFT) [14–16] with the ω B97XD functional [17] in combination with

102 6-31G(d,p) and LANL2DZ [18] basis sets. This functional was chosen as it has long-
103 range terms and can calculate weak dispersion interactions [17]. Gaussview5.0 [19] was
104 used for visualization. The minimum nature of all optimized structures was verified with
105 frequency calculations at the same level. The time-dependent DFT (TD-DFT)
106 calculations were performed to calculate the UV-vis absorption spectra (n = 80 states)
107 and molecular orbital energies using the ground-state optimized geometries. TD-DFT
108 calculations were performed with Becke's 3 parameter exchange and Lee-Yang-Parr
109 correlation functionals (B3LYP) [20] and were repeated with CAM-B3LYP (Coulomb-
110 Attenuating Method) [21] and ω B97XD functionals in combination with 6-31G(d,p) and
111 LANL2DZ basis sets to obtain UV-vis spectra and both computational results were
112 compared with experimental UV-vis absorption spectra. To mimic the real systems, all
113 calculations were done in solution. Polarizable Continuum Model (PCM) [22] was used
114 in all DFT and TD-DFT calculations to investigate solvent effects on the electronic
115 transitions in solution.

116 The natural bonding orbitals (NBO) calculations were performed using NBO 3.1
117 program [23] as implemented in Gaussian 09 package. The second-order Fock matrix
118 was used to evaluate the donor-acceptor interactions on the NBO basis.

119 **3 RESULTS AND DISCUSSION**

120 **3.1 Synthesis and Characterization**

121 The synthesis of **1** is illustrated in Scheme 1.

The ESI-MS spectrum (Fig.S1) of **1** shows the mono cationic peak at m/z 619.0 $[\text{Pt}(\text{L})+\text{Cl}]^+$ ($\text{C}_{24}\text{H}_{16}\text{N}_6\text{PtCl}$). The major peak at m/z 697.1 is attributed to $[\text{Pt}(\text{L})+\text{Cl}+(\text{CH}_3)_2\text{SO}]^+$ ($\text{C}_{26}\text{H}_{22}\text{N}_6\text{SOPtCl}$) which confirms the solvated of the ion in solution as revealed by the X-ray analysis. The ^1H NMR spectrum of **1** is shown in Fig. S2. The most striking feature of the spectrum is that due to C_2 symmetry in solution, only one set of signals assigned to the two halves of the 2,2'-bipyridine unit is observed. This is confirmed by the integration of the protons since the number of protons present in the spectrum is well-matched with the stoichiometry of **1**. The ^1H NMR spectrum is very much similar to those of the copper(I) and silver(I) complexes of the ligand [2]. In the present spectrum, the signal corresponding to the N-H proton is missing due to exchange with the deuterated solvent which resonates at 3.85 ppm for HOD. The comparison with the free ligand [1] indicates that the signals corresponding to the py protons in **1** undergo deshielding (the signals for the py protons in L appear at 8.47 as a doublet, 8.33 as a doublet, and 7.56 as a quartet). The signals for the py protons in the NMR spectrum of the zinc(II)-bis-complex [1] appear at 8.5 ppm as a quartet, 7.8 ppm as a triplet, and 7.7 ppm as a doublet, respectively. It is clear that upon coordination to the metal center, substantial changes relative to the free ligand are observed. The most pronounced deshielding is observed in the spectrum of **1** compared with those of the Zn(II) [21], and Cu(I) and Ag(I)-bis-complexes [2].

143 The signals corresponding to the benzene protons in the present structure also show deshielding
144 in comparison to those of the free ligand and Zn(II) [1], and Cu(I), and Ag(I) complexes. One
145 should bear in mind that L in the *bis*-complexes, such as Zn(II), Cu(I), and Ag(I) [2],
146 coordinates to the metal center through only the bim N atoms, and the py N atoms remain as
147 uncoordinated [2]. The significant deshielding of the py protons in the present spectrum of **1**
148 may be ascribed to the coordination of the py N atom to the Pt(II) center as revealed by the X-
149 ray analysis (*vide infra*).

150 The IR spectrum of **1** is shown in Fig. S3, The N-H stretch appears at 3576 cm⁻¹, which is
151 consistent with that reported for benzimidazole [24]. The weak band at 3312 cm⁻¹ is assigned
152 to the OH stretching of the bound water molecule [24]. The parental absorption is observed at
153 the lower frequency at 1616 cm⁻¹ may be assigned to the bending vibration of the OH, as well.
154 The band at 3156 cm⁻¹ may be assigned to the N-H bending vibration [25], while the band at
155 3065 cm⁻¹ is readily assigned to the aromatic C-H stretching vibration. The py and bim ring
156 stretching vibrations appear in the region of 1590-1520 cm⁻¹. The out-of-plane bending modes
157 for the py and bim rings are observed below 1485 cm⁻¹, and those related to bending modes of
158 the Ar-H appear in the region of 816-707 cm⁻¹.

159 The UV-vis absorption and emission spectra of **1** in DMSO are depicted in Fig. 1. In the UV
160 spectrum, the high-intense absorption bands at $\lambda \approx 283$ nm are assignable to the intraligand
161 $\pi \rightarrow \pi^*$ transitions of the free ligand [26]. The relatively low-energy absorptions bands
162 originating from metal-to-ligand charge-transfer (MLCT) transitions may lie underneath the
163 broad absorbance as suggested for the related platinum(II) complexes [6,26]. Fig. 1 also depicts
164 the emission spectra of **1** with the emission maxima at 450 nm. The emission is similar to the
165 free ligand [2] and the related coordination compounds [1]. The emission intensity increases
166 upon coordination to the metal ion as observed for the related cases [1,2]. The enhanced
167 luminescence was attributed to the rigidity of the coordinated ligand which reduces the

168 nonradiative decay in the excited state [1]. As revealed by the X-ray analysis, the compound
169 forms adduct with DMSO in the solid-state (vide infra). The emission band at about 450 nm is
170 assignable to the intraligand charge-transfer (ILCT) transitions since similar emission bands are
171 observed for the analogous Zn(II)-*bis*-complex [1] and also for Ag(I) and Cu(I) complexes [2].

“Fig. 1”

3.2. Structure description of **1**

176 The crystal structure of **1** is shown in Fig. 2. The experimental and calculated bond lengths and
177 angles are listed in Table S1 and S2, respectively. The hydrogen bonding parameters are given
178 in Table 2. The SCXD analysis reveals a discrete mononuclear neutral complex, **1**, which
179 consists of L acting as a bidentate ligand through the N atom of the py and bim rings and two
180 Cl atoms, and an adduct of DMSO. This new complex features very interesting coordination
181 modes. The transition metal complexes of the ligand with Cu(II) [4], Zn(II) [1], Ag(I), and Cu(I)
182 [2] have been published. The ligand in all these complexes invariably acts as a bidentate
183 *bis*(imidazole) donor ligand coordinating to the metal center solely through the N atoms of the
184 bim rings, whereas the py N atoms remain uncoordinated. The present study reports the
185 unprecedented coordination compound of the ligand with a Pt(II) ion. In the present structure,
186 the ligand acts in a bidentate fashion and binds to the metal center via both the py and bim rings
187 as depicted in Fig. 3. The Pt atom adopts a distorted square-planar coordination environment
188 with two N atoms from the ligand (one N atom from py2 and one N atom from bim1 forming a
189 seven-membered ring) and two chlorine atoms to form a *cis*-PtN₂Cl₂ chromophore as depicted
190 in Fig. 3. Pt1 is in near ideal square planar geometry, with the mean deviation from the plane
191 defined by Pt1 and its coordinated atoms being 0.002(1) Å. The angles of N(4)–Pt(1)–Cl(2)
192 177.76(8)° and N(1)–Pt(1)–Cl(1) 177.99(8)° indicate a very small degree of distortion, while

193 the N1–Pt1–N4 87.96(11)° and C11–Pt1–C12 91.53(3)° bite angles are also very close to the
194 ideal for a perfect square-planar geometry. These angles are consistent with the analogous metal
195 complexes of the py-bim ligands [27–29]. The Pt–N1 (bim) distance of 2.016(3) Å is slightly
196 shorter than Pt–N4 (py) 2.023(3) Å, as found in other platinum(II)-pyridyl-benzimidazole
197 complexes [4]. The slight difference in the Pt–Cl bond lengths, Pt–C11 2.3032(8) Å and Pt–C12
198 2.3009(8) Å, reflects the *trans*-effect of the imidazole chromophore, which is more basic than
199 pyridine and thus more strongly coordinates to the metal center. The free ligand in the solid-
200 state adopts a *trans*-conformation with two bim fragments on the opposite sides of the 2,2'-
201 bipyridine backbone [4], with py-py and bim-bim dihedral angles reported as 72.5° and 99.3°,
202 respectively. The large angles are accounted for the intramolecular N–H···N hydrogen bonds
203 [4]. In **1**, the plane of the py rings are inclined at 60.36°, whereas the py and bim rings are
204 inclined at 40.06° and 45.89° respectively. These dihedral angles are dramatically different to
205 those observed for the related distorted tetrahedral complexes [2]. The smaller dihedral angles
206 in **1** are obviously due to the coordination of the bim and py rings residing on the different
207 halves of the molecule. This coordination mode of the ligand makes it possible to accommodate
208 a square-planar complex. The binding of the ligand to the Pt atom forms a seven-membered
209 ring. The molecular structure of **1** is stabilized by intermolecular complementary hydrogen
210 bonds between the py and bim rings (N–H_(bim)···N_(py)) in the neighboring molecules as
211 illustrated in Fig. 4. The uncoordinated benzimidazole group forms an intramolecular hydrogen
212 bond with the DMSO molecule through N–H_(bim)···O (Table 2). The molecular units in the
213 lattice are held together in a head to tail fashion as a dimer through N–H···N hydrogen bonds
214 with the R_2^2 (14) graph-set motif.

24

25 230

26

27 231 The normalized contact distance based on d_e (distance from the Hirshfeld surface to the nearest

28

29 232 nucleus outside the surface), d_i (distance to the nearest nucleus inside the surface), and the van

30

31 233 der Waals radius of the atom are shown. In d_e and d_i , the shortest, intermediate, and long

32

33 234 distances are denoted by red, green, and blue colors respectively (Fig. S4).

34

35 235 A shape index in the range of -1 to 1 a.u. for the compound shows triangular red regions around

36

37 236 the rings, indicating the presence of stacking interactions. Curvedness mapping for the

38

39 237 compound has regular green sections indicating the presence of parallel stacking interactions

40

41 238 (Fig. S4).

42

43 239

44

45 240 3.3. DFT studies

46

47 241 The optimized geometries of the most stable structures for **1** as a monomer and dimer are shown

48

49 242 in Fig. 6. The monomers are interconnected with each other by intermolecular H-bonds to form

50

51

52

53

54

55

56

57

58

243 a dimer with a helical shape. The experimental and the calculated bond distances and angles
244 are listed in Table S1 and Table S2 respectively for comparison. Fig. S5 provides a better
245 understanding of all the differences in the distances and Table 3 shows the selected bond lengths
246 [\AA] and angles ($^\circ$) for the monomer and dimer for comparison calculated using ω B97XD
247 functional with 6-31G(d,p) and LANL2DZ (for Pt) basis sets.

“Fig. 6”

251 The experimental and calculated bond distances are generally similar for the monomer
252 molecule. The small deviations in the calculated data from the experimental XRD data may be
253 due to the solvent effects in the optimized structure. Additionally, while the calculations are
254 carried out for a single molecule in DMSO using an implicit solvent model, the experimental
255 measurements are in the solid-state with the presence of neighboring molecules.

256 Bond distances in the dimer are slightly different than those of the initial monomer. However,
257 the N-H distances are slightly larger in the dimer structure compared to the crystal structure and
258 the calculated monomer (1.008 \AA in the monomer, 1.029 \AA in the dimer, N(6)–H(6N); from
259 1.009 \AA to 1.047 \AA in the dimer N(2)–H(2N) in Table 3).

260 The H-bonding of the monomer with the neighboring molecule lengthens the N-H bond
261 distance in the monomer. Hydrogen bonds are observed between N-H \cdots N in the dimer and N-
262 H \cdots O with the adjacent DMSO molecule (H(6N) in bim2...N(3)' in py1', N(3) in py1...H(6N)'
263 in bim2', H(2N) in bim1...O(1), and H(2N)' in bim1'...O(1)'). Intermolecular H-bonding
264 interactions stabilize the framework structure.

265 Changes in the bond and torsion angles between the monomer and dimer are also observed. The
266 Pt atom preserves its square planer structure. The Pt center is not coplanar with its neighboring
267 pyridines (py1 and py2) and benzimidazole (bim1). There are small differences in the bond

268 angles between the monomer and dimer. For example, the N(1)–Pt(1)–N(4) angle of 87.92° in
269 the monomer is found to be 85.12° in the dimer. Significant changes are observed in the dihedral
270 angles. While the dihedral angle between py1 and py2 is 59.55° in the monomer structure, it is
271 65.03° in the dimer structure. It can be said that due to the interaction between the molecules in
272 the dimer structure, more deviation from the plane is observed. The dihedral angle between py1
273 and bim1 remains approximately the same. The torsion angle between py2 and bim2 decreases
274 from 44.95° to 29.71° and approaches a planar geometry.

“Table 3”

276
277 Table S3 shows the dipole moments (μ , in Debye), the sum of total electronic energies and zero-
278 point energies (E+ZPE), the sum of electronic energy and thermal Free Energy Correction
279 (E+ Δ G) and stabilization energies at zero Kelvin (Δ E) and room temperature ($\Delta\Delta$ G) for ground-
280 state geometries in water for **1** and the dimer. Considering the energy values related to the
281 stability of the dimer structure, it has been observed that the dimer structure is more stable
282 (negative Δ E and $\Delta\Delta$ G values). Besides the dimer structure being more polar than the monomer
283 structure, both monomer and dimer have a high dipole moment.

284
285 Additionally, the NBO charge distribution for **1** and the dimer structures have been carried out
286 by DFT levels (Table S4) to understand the changes in charge distribution of the systems upon
287 H-bond formation of the molecules. It can be seen from the charge layout of the monomer and
288 dimer molecule that N atoms (N6 or N55 in Fig. S6) participating in the H-bond in the dimer
289 structure have increased their electron donor properties (charges for N6 in the monomer -0.461,
290 in the dimer -0.499). It clear that the N atoms have more donor electron ability in the dimer
291 form than that of the monomer (Fig. S7).

292

293 NBO analysis was also used to probe hydrogen bonding, the hyper conjugative interactions
294 responsible for the compound stability and charge transmission between the electron donor (i)
295 and acceptor (j) by Fock matrix analysis. For the dimer molecule LP(N) $\rightarrow\sigma^*(\text{N-H})$ and
296 LP(O) $\rightarrow\sigma^*(\text{N-H})$ were observed with promising stabilization energies as presented in Table S5
297 and Fig. S8 (LP: lone pair electrons).

298
299 The molecular electrostatic potential (MEP) map is useful to find the suitable regions for
300 electrophilic and nucleophilic attacks on the molecule. The total electron density was calculated
301 using the NBO charge distribution. Fig. S9 shows the MEP of the dimer in DMSO mapped in
302 the range between -0.126 a.u. and +0.126 a.u. Red colors of the electrostatic potentials refer to
303 more electron density which could be favorable positions for electrophilic attacks. The negative
304 charges are mostly localized on the electronegative Cl, O, and N atoms. C and H atoms with
305 blue and green colors exhibiting mostly positively charged regions (electron-deficient zones).
306 Therefore, it is more susceptible to nucleophilic attacks by other species.

307 Fig. S10 shows the differences of UV-Vis absorption spectra between the calculated spectra
308 with different functionals (B3LYP, CAM-B3LYP, and ωB97XD) and the experimental one.
309 CAM-B3LYP results are used in the discussion since they are more consistent with the
310 experimental spectra. Fig. 7 shows the calculated and experimental UV-vis absorption spectra
311 for the dimer in DMSO. The selected electronic transitions and the corresponding orbitals for
312 the compound are displayed in Table S6 and Fig. S11, respectively.

“Fig. 7”

314
315 There are d-d transitions, $\pi\text{-}\pi^*$, $n\text{-}\pi^*$ charge transfer (CT) transitions, metal-to-ligand charge
316 transfer (MLCT), and ligand-to-metal charge transfer (LMCT) types upon excitation for the
317 dimer. The maximum peak at 293.1 nm displays a $\pi\text{-}\pi^*$ intra-ligand transition from HOMO of

318 bim2 to LUMO+3 of py2 rings (CT1). At wavelengths between 335 nm and 386 nm, forbidden
319 d-d transitions can be seen with weak oscillator strengths. Due to the very small intensity of the
320 peaks, they could not be observed in the experimental spectrum. The chlorine atoms are also
321 excited, with d orbitals in the same region. Again, in this region, at 358.3 nm, LMCT occurs
322 from bim to Pt. MLCT from the Pt to the py and bim rings is observed at 250 nm. In general,
323 the electronic transitions correspond to the transitions between bim and py between 250 and
324 300 nm. The locally excited state of benzimidazole (LE3) is observed with MLCT at 264.5 nm.

325 4 CONCLUSION

326 The research on the synthesis and characterization of the new coordination compound of
327 platinum(II) with a sterically hindered ligand, 3,3'-bis(NH-benzimidazol-2-yl)-2,2'-bipyridine
328 has resulted in unprecedented *cis*-[Pt(L)Cl₂].DMSO. To the best of our knowledge, it is the first
329 compound where this ligand coordinates to the metal center in a *cis*-disposition through both
330 the pyridine and benzimidazole N atoms to afford a square-planar PtCl₂N₂ complex. The
331 compound is solvated in the solid-state [Pt(L)Cl₂].DMSO. The molecular units are
332 interconnected with each other in a head to tail fashion through the complementary N–H···N
333 hydrogen bonds with a R_2^2 (14) graph-set motif. The molecular structure is further stabilized by
334 intermolecular N–H···O hydrogen bonding with the solvent molecule. The compound exhibits
335 blue luminescence in solution. DFT optimized structure and the crystal structure of the
336 monomer are consistent with each other. Hirshfeld surface analysis and NBO analysis show
337 that the dimer structure is stabilized by H-bond formation. Electronic energy calculations and
338 Gibbs free energy calculations confirm the stable dimer formation.

Empirical formula	C ₂₆ H ₂₀ Cl ₂ N ₆ OPtS	
Formula weight	730.53	
Temperature	120(2) K	
Wavelength	0.71073 Å	
Crystal system	Triclinic	
Space group	P-1	
Unit cell dimensions	a = 9.9136(3) Å	α = 109.7700(10)°.
	b = 12.5634(3) Å	β = 111.1540(10)°.
	c = 12.8377(3) Å	γ = 101.6710(10)°.
Volume	1303.93(6) Å ³	
Z	2	
Density (calculated)	1.861 Mg/m ³	
Absorption coefficient	5.698 mm ⁻¹	
F(000)	708	
Crystal size	0.14 x 0.05 x 0.05 mm ³	
Theta range for data collection	3.24 to 27.50°.	
Index ranges	-12 ≤ h ≤ 12, -16 ≤ k ≤ 15, -16 ≤ l ≤ 16	
Reflections collected	27964	
Independent reflections	5957 [R(int) = 0.0321]	
Completeness to theta = 27.50°	99.6 %	
Absorption correction	Semi-empirical from equivalents	
Max. and min. transmission	0.7637 and 0.5026	
Refinement method	Full-matrix least-squares on F ²	
Data / restraints / parameters	5957 / 0 / 344	
Goodness-of-fit on F ²	1.068	
Final R indices [I > 2σ(I)]	R1 = 0.0255, wR2 = 0.0641	
R indices (all data)	R1 = 0.0272, wR2 = 0.0653	
Largest diff. peak and hole	1.340 and -1.753 e.Å ⁻³

a: stabilization energy (energy of hyperconjugative interactions); b: Energy difference between donor and acceptor i and j NBO orbitals; c: Fock matrix element between i and j NBO orbitals

d: valence lone pair electron on O and N atom; E(2) = $q_i [(F(i,j))^2/E(j)-E(i)]$ equation defines stabilization energy related to second order perturbation theory.

Fig. S9. Molecular electrostatic potential surface map for the dimer compound in DMSO calculated at wB97XD/6-31G(d,p)/LANL2DZ level (isovalue is 0.02 a.u.). Colours represent electron density: red, electron-rich; yellow, slightly electron-rich region; green, neutral; light blue, slight electron deficiency; blue, electron deficiency.

Fig. S10. Experimental and calculated (with different functionals) normalized UV-Vis absorption spectra for the dimer in DMSO

Table S6. Electronic transitions (λ_{ex}) corresponding to vertical excitation energies (ΔE), oscillator strengths (f), excitation character, molecular orbitals, and their % contributions of dimer in DMSO calculated with TD-DFT at CAM-B3LYP/6-31G(d,p)/LANL2DZ levels
