A novel butterfly-shaped tetracarboxylic acid [9,9'-methylene-bis(9-methylfluorene-2,7-dicarboxylic acid), H₄L] featuring a co-facial bifluorene core was designed and synthesised. Reactions of H₄L with Cd^{II} produced the luminescent supramolecular frameworks **2** and **3**, with different dimensionalities and wingspans of L⁴⁻. Their solid-state emission properties were rationalised based on the torsional dynamics of the facing bifluorene units by means of X-ray diffraction analysis and TD-DFT calculations.

Introduction

Fluorene derivatives have been extensively studied in the past years owing to their versatile role in materials science, and particular interest has been devoted to polyfluorenes due to their electroactive and photoactive nature that allows for the preparation of blue-light emitting diodes with tunable electronic and emission properties.^{1–6} Oligo- and polyfluorenes were employed as models in the design of functional polymeric materials for the understanding of excimer formation and hole stabilization in π -stacked assemblies.^{7–12} Supramolecular constructs originating from the interaction of fluorene derivatives and metal ions were prepared giving rise to coordination polymers (CPs) and metal-organic frameworks (MOFs) featuring remarkable properties allowing for their application as separating agents,^{13–15} sensors^{16–18} and electro-phosphorescent materials.¹⁹ The key role of fluorene derivatives in the

preparation of sensing materials lies in the variation of their photoluminescent response according to the nature of the interacting guests. The role of poly-fluorenes as supramolecular synthons is still largely untapped, and all the above-cited examples include either single fluorene or spiro-bifluorene derivatives.^{20,21} Belonging to the above-mentioned class of poly-fluorene derivatives, co-facial bifluorenes can provide additional advantages when applied to crystal engineering, since the overlapping extent of the facing fluorene units may potentially lead to variations in the fluorescent response. The chemical and geometrical features of the substituents introduced in the fluorene rings influence in turn the face-overlapping and the resulting emission properties of the material.⁷ Moreover, the interaction with metal nodes in the self-assembly could itself affect the geometry adopted by the organic linkers leading to unprecedented architectures and modulated fluorescence properties. Therefore, we designed a brand new co-facial bifluorene-based linker, 9,9'-methylene-bis(9-methylfluorene-2,7-dicarboxylic acid), H₄L, as a tecton for the assembly of fluorescent supramolecular networks. The unprecedented design of H₄L with four carboxylic acid groups distributed on two methylene-bridged fluorene units opens new perspectives in the preparation of robust and optically active porous materials based on polycarboxylic acids.²²

Results and discussion

Synthesis and structural characterization

The precursors **1b** and **1c** were prepared starting from the commercial compound **1a**, as previously described.⁷ The

Scheme 1 Synthetic steps leading to H₄L starting from compound 1a.

linker H₄L was prepared according to the synthetic route outlined in Scheme 1 by adapting a procedure we previously reported for the synthesis of siloxane-based linkers.²³

The tetrabrominated compound **1c** and the linker H₄L were structurally characterized by means of single crystal X-ray diffraction (XRD) analysis (Tables S1 and S4†). Compound **1c** crystallises in the monoclinic space group *P*2₁/*c* with a single molecule in the asymmetric unit (Fig. S1†). The two fluorene units are almost co-facial with an angle $\alpha = 14^\circ$ between the planes of the fluorene moieties and a dihedral angle $\tau = 25^\circ$ calculated along the torsional coordinate *via* methylene linkers, in a “closed wing” configuration (see Fig. 1 for the α and τ definitions).

The outer rings of both fluorene units show intra- and inter-molecular π - π interactions with centroid distances of 3.63 and 3.73 Å, respectively, leading to face-to-face dimeric constructs packed along the *a*-axis through Br \cdots Br weak contacts in a herringbone pattern leading to a 2D network (Fig. S2 and S3†).

The tetracarboxylic acid H₄L crystallises in the triclinic space group *P* $\bar{1}$ with one molecule in the asymmetric unit (Fig. 2A).

This butterfly-shaped compound features an opening angle $\alpha = 20^\circ$ wider than that found for **1c**.

The compound H₄L features four carboxylic groups, located at the 2 and 7 positions of each fluorene moiety, almost coplanar to the respective fluorene moieties [torsion angles in the range 5.8(5)–13.7(3)°]. The HBs involving the carboxylic groups of both fluorene moieties induce a dramatic decrease of τ angle ($\tau = 5^\circ$) and a larger overlap between the co-facial fluorene units, which results in intramolecular (*a* and *b* in Fig. 2B) and intermolecular (*c* in Fig. 2B) π - π interactions featuring centroid distances of 3.47, 3.66, and 3.89 Å, respectively, that stack the chains in 2D layers (Fig. 2B). The layers interact by means of weak HBs in an overall 3D network (Fig. S4 in the ESI†).

Upon deprotonation, the four carboxylic groups are potentially available for metal coordination. H₄L was therefore reacted with Cd(NO₃)₂·4H₂O in a 1:2 molar ratio in a dimethylacetamide (DMA)/H₂O mixture (2:1 *v/v*) at 90 °C for 24 h. The reaction yielded colourless crystals

characterized by single-crystal XRD as the CP $[\text{Cd}_2\text{L}(\text{H}_2\text{O})_6 \cdot 2\text{H}_2\text{O}]_\infty$ (**2**). Compound **2** crystallised in the triclinic space group $P\bar{1}$ with a single L^{4-} unit, two Cd^{II} ions, six coordinated and two co-crystallised water molecules in the asymmetric unit (Fig. 3A and Table S2†).

Both Cd^{II} ions are hepta-coordinated in a pentagonal-bipyramidal geometry: the five equatorial positions are occupied by two chelating carboxylates and one water molecule; two axially bound water molecules complete the coordination sphere around the metal ions (Fig. 3A).

The tetracarboxylate bifluorene unit features α and τ angles of 19 and 25° and intramolecular centroid distances of 3.77 and 3.70 Å, respectively, slightly longer than those found in H_4L , due to the increased displacement between the facing bifluorene planes. The L^{4-} spacers bridge couples of symmetry-related Cd1 and Cd2 ions through the four carboxylate anions giving rise to infinite ribbons (Fig. 3B). The ribbons pack through strong HB interactions involving the carboxylate oxygen atoms and both coordinated and co-crystallised water molecules (Fig. S5 and S6 and Table S5 in the ESI†).

A 1:2 molar ratio reaction between H_4L and $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ in the same DMA/ H_2O (2:1 v/v) mixture was also performed at 120 °C affording crystals of two different morphologies derived *via* the concurrent formation of the previously described CP **2** and a 3D-MOF with the formula $[\text{Cd}_2\text{L}(\text{H}_2\text{O})_3 \cdot 3\text{H}_2\text{O}]_\infty$ (**3**).† Compound **3** crystallised in the orthorhombic non-centrosymmetric space group $\text{Cmc}2_1$. The

† A solvent mask was calculated, and 250 electrons were found in a volume of 1220 Å³ per unit cell. This is consistent with the presence of 24 H_2O molecules per unit cell.

Fig. 4 Crystal structure of MOF **3**: A: asymmetric unit. B: Cd coordination environments. Interactions are summarised in Table S6.† ⁱ = $3/2 - x, 1/2 + y, z$; ⁱⁱ = $3/2 - x, 3/2 - y, -1/2 + z$; ⁱⁱⁱ = $2 - x, 2 - y, -1/2 + z$; ^{iv} = $3/2 - x, 1/2 + y, z$; ^v = $2 - x, y, z$; ^{vi} = $1/2 + x, 3/2 - y, -1/2 + z$.

asymmetric unit comprises halves of four crystallographically independent Cd^{II} ions, a fully deprotonated L^{4-} ligand and five coordinated water molecules, four of which lie on special positions (Fig. 4A and Table S3†).§ The linker shows angles α and τ of 7 and 22°, respectively, with intramolecular centroid distances of 3.56, 3.24 and 3.62 Å.

The four carboxylate groups of L^{4-} coordinate four independent cadmium ions adopting three different coordination modes (see Scheme S1†): I) chelating; II) chelating/bridging; III) bridging. A detailed description of the different coordination geometries around each cadmium ion is shown in Fig. 4B.

Cd1, Cd3, and Cd4 are hepta-coordinated and adopt a capped trigonal prismatic geometry constructed by six differently coordinated symmetry related carboxylates and one capping H_2O molecule. The Cd2 ion is hexa-coordinated into a distorted octahedral geometry by two μ_2 -oxygen atoms from two different L^{4-} anions and four water molecules (Fig. 4B and Table S6†). The described coordination environments generate a MOF with S-shaped (sinusoidal) secondary building units (SBUs) formed by edge-shared Cd-polyhedra of different shapes (Fig. 5A).²⁴ The overall three-

Fig. 5 A: Packing view of the infinite sinusoidal arrangement formed by edge-shared Cd-polyhedra. B: Packing diagram along the *c*-axis.

dimensional MOF **3** shown in Fig. 5B is characterized by ellipsoidal channels with openings of approximately $8.5 \times 3 \text{ \AA}^2$ that occupy 17% of the unit cell volume.

Three disordered water molecules are present in the asymmetric unit and were subjected to the SQUEEZE routine. Unfortunately, since compound **3** was not obtained pure, stability on evacuation, porosity measurements, and gas sorption studies were not carried out.

Powder XRD measurements were carried out on the solid-state products obtained by different reactions of H_4L and $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ performed under different experimental conditions. The experimental results, compared with the simulated patterns calculated from the single crystal XRD data of CP **2** and MOF **3** (Fig. S7†), show that depending on the reaction temperature, either pure CP **2** (90 °C) or a mixture of **2** and **3** (120 °C) is formed (named **2 + 3** subsequently). All attempts to obtain a bulk sample of pure **3** failed. TGA analyses performed on **2** and **2 + 3** show that both samples had a significant weight loss in the range 120–170 °C suggesting a decomposition of both compound **2** and mixture **2 + 3**. Accordingly, the DSC measurements show endothermic processes in the same temperature range (Fig. S8†).

Photophysical measurements

The absorption and emission spectra of the synthesised compounds were recorded both in solution and in the solid state for H_4L and in the solid state for **2** and mixture **2 + 3**, whilst no emission was observed for **1c**. In DMSO solution, H_4L featured a structured absorption band at about 310 nm. A similar spectral shape could be seen in the diffuse reflectance spectrum, showing a broad absorption in the range 300–380 nm, with a maximum at about 335 nm (Fig. S9†). Compound **2** and mixture **2 + 3** display diffuse reflectance spectra very similar to that of H_4L (Fig. S10†).

Excitation at 303 and 372 nm led to strong fluorescence emission bands at 436 and 491 nm in DMSO solution and in the solid-state, respectively, for H_4L (Fig. S9†). Therefore, in the solid-state both the absorption and emission energies are bathochromically shifted as compared to those recorded in DMSO solution. A comparison with the solid-state emission properties of the mono-fluorene derivative 9,9'-dimethylfluorene-2,7-dicarboxylic acid,²⁵ reported at 410 nm, evidences a significant difference in the emission wavelength on passing from the mono- to the bi-fluorene derivative, tentatively ascribable to the co-facial arrangement of the fluorene units ($\tau = 5^\circ$). A comparison of the normalized emission spectra of H_4L , **2** and **2 + 3** (Fig. 6) shows a shift of the emission band to 433 nm for both cadmium supramolecular constructs **2** and **2 + 3**.

It is worth pointing out that differences of only 5 nm in the solid-state emission wavelengths were evidenced on passing from the above mentioned 9,9'-dimethylfluorene-2,7-dicarboxylic acid to the corresponding zinc and cadmium supramolecular constructs.²⁵ The significant variation observed in the case of our systems can be tentatively explained by taking into account the increased displacement between the facing fluorene planes found in cadmium supramolecular constructs as compared to free H_4L ($\tau = 5, 25$ and 22° for H_4L , **2** and **3**, respectively; see above).

Fig. 6 Normalised solid-state emission spectra determined for H_4L (blue), **2** (green) and mixture **2 + 3** (red). $\lambda_{\text{ex}} = 372, 330,$ and 340 nm for H_4L , **2**, and **2 + 3**, respectively.

TD-DFT calculations

The absorption and emission properties of H_4L were elucidated by means of DFT²⁶ and TD-DFT calculations (PBE0//def2-SVP; see the Experimental section and Tables S7–S9†) carried out in the gas phase and in DMSO by using the polarizable continuum self-consistent reaction field model in its integral-equation formalism (SCRf IEF-PCM).²⁹ Notably, in the gas phase the four carboxylic groups show orientations very close to those determined by XRD, with torsion angles with respect to the relevant fluorene moieties in the range 2.7–10.5°. The torsion angle between the two fluorene units calculated at the optimised geometry for H_4L is $\tau = 26.0^\circ$, *i.e.*, it is very similar to the structural value of **1c**. This similarity suggests that the crystal-packing interactions and, in particular, the strong HBs involving the carboxylic acids, could be responsible for the small τ value of the facing fluorene units found in the crystal structure of H_4L , which was proved to be directly related to the energies of the ground (GS) and excited states (ES) involved in the absorption and emission processes calculated for H_4L . In Fig. 7 a quantitative Jablonski diagram

Fig. 7 Quantitative energy diagram for the absorption and emission processes calculated for H_4L . The energies of the GS (red curve) and ES #1 (black line) are depicted as a function of the torsion angle τ . E_{GS} and E_{ES} are the minimum energies of the ground state and excited states, respectively (neglecting ZPE corrections). Arrows schematically represent the excitation and relaxation paths (see Experimental section and Table S8† for calculated absorption and emission energies and wavelengths).

for the singlet states calculated for H_4L at the optimised geometry is depicted.

The allowed vertical transition lying at the lowest energy (GS \rightarrow ES #4) is calculated for H_4L at $E_{abs} = 4.162$ eV (corresponding to $\lambda_{abs} = 297.9$ nm) in the gas phase. In DMSO, the corresponding excitation involves the GS \rightarrow ES #3 transition ($E_{abs} = 4.089$ eV; $\lambda_{abs} = 303.2$ nm) in excellent agreement with the experimental value ($\lambda_{abs} = 310$ nm; see above). These transitions are assigned to Kohn–Sham (KS) HOMO–1 \rightarrow KS-LUMO+1 and KS-HOMO \rightarrow KS-LUMO one-electron π – π^* excitations [see Fig. S11† and Table 1; natural transition orbitals (NTOs)³⁰ involved in the GS \rightarrow ES #4 transition are depicted in Fig. S12†], *i.e.*, they involve MOs delocalised on both fluorene units of H_4L . To investigate the emission properties of H_4L , the geometry of ES #1 was optimised, and the emission energy E_{fluo} and wavelength λ_{fluo} were calculated (see the ESI† for details; $\lambda_{fluo} = 450.2$ and 468.2 nm in the gas phase and DMSO solution, respectively, Table S8†). According to Kasha's rule,³¹ after internal conversion ES #4 \rightarrow ES #1 and vibrational relaxation of the first excited state, luminescent emission occurs from ES #1 to GS.

The most remarkable difference between the metric parameters optimised for the GS and ES #1 involves the τ angle (Fig. 1; $\tau = 26.0$ and 7.7° for GS and ES #1, respectively in the gas phase; $\tau = 21.6$ and 2.3° for GS and ES #1, respectively in DMSO), indicating that vibrational relaxation processes result in a variation of the relative orientation of the two fluorene units. After the emission due to the radiative relaxation ES #1 \rightarrow GS, the GS undergoes a vibrational thermalization to the equilibrium geometry. As previously observed, the XRD analysis showed that in the solid state H_4L is locked in a co-facial conformation of the two fluorene moieties with a τ angle (5°) that is very close to that optimised for ES #1 (7.7°), thus possibly accounting for the difference in the transition energies determined in the solid state with respect to the corresponding values recorded in DMSO (see above).

DFT calculations were extended to the $[Cd_4L_2(H_2O)_{16}]$ model complex (**4**, Fig. S13†), mimicking a portion of CP 2. In complex **4**, the L^{4-} anion bridges four Cd^{II} metal ions by means of the four carboxylate groups, the water molecules completing a distorted octahedral coordination at each metal ion. Notably, the frontier KS-MOs calculated for complex **4** at the optimised geometry ($\tau = 24.43^\circ$) are π -in-nature MOs exclusively localized on the aromatic portion of the bifluorene moieties of the L^{4-} anion (Fig. S13†). Accordingly, excitation processes are completely ligand-centred and occur at energy values very similar to that calculated for H_4L . In fact, the first allowed electronic absorption at the lowest energy involves the transition from the GS to ES #4 ($E^{GS-ES\#4} = 3.941$ eV; $\lambda^{GS-ES\#4} = 314.6$ nm; $f = 0.959$; Table S9†) and this is mainly due to the KS-HOMO–1 \rightarrow LUMO and HOMO \rightarrow LUMO+1 monoenergetic excitations (the main NTOs involved in the GS \rightarrow ES #4 transition are depicted in Fig. S14†). Finally, neglecting the vibrational relaxation of ES #1

Table 1 Energy E_{abs} (eV) calculated for singlet-singlet electronic transitions, the corresponding wavelengths λ_{abs} (nm), oscillator strengths f and the main contributing mono-electronic excitations for the four lowest excited states calculated on H_4L in the gas phase and DMSO at the TD-DFT level

of H_4L and **4**, the lowest energy of the GS → ES #1 transition calculated **4** with respect to H_4L might account for the blue-shift of **2** and the **2** + **3** mixture as compared to the starting ligand H_4L (Fig. 6).

Conclusion

The results reported on the new bifluorene-tetracarboxylate 9,9'-methylene-bis(9-methylfluorene-2,7-dicarboxylic acid) (H_4L) and its CP (**2**) and MOF (**3**) assemblies show the potential of the spacer in the realm of supramolecular chemistry due to its structural features and intrinsic fluorescence and of the possibility of varying the emission properties either by changing the carboxylate coordination environments or by acting on its geometrical features.

In summary, the peculiar solid-state co-facial constrained conformation of H_4L (absent in DMSO solution) can be considered responsible for its emission at higher energy as compared to mono-fluorene derivatives and to the Cd^{II} complexes **2** and **3**. This suggests not only that the emission energies of bifluorene derivatives can be fine-tuned by structural modifications affecting their rigidity but also that subtle structural modifications, such as the introduction of terminal carboxylates, can be fundamental in determining the resulting emission energies.

The presented ligand can thus be considered the first precursor of a novel family of π -stacked carboxylate synthons to be used in crystal engineering suitable for sensing applications. Further work is being conducted in our labs at both the theoretical and experimental levels to study the reactivity of H_4L and structurally related ligands with different cations and anions in solution and in the solid state.

Experimental

Materials

All chemicals, reagents, and solvents were purchased from Sigma-Aldrich, TCI, Fluorochem, or VWR Chemicals and used as received without any further purification if not otherwise stated.

Spectroscopic characterisation

FT-Infrared spectra were recorded on a Thermo Nicolet 5700 spectrometer on KBr pellets.

Mass spectra were recorded on a Waters LCT Premier (ES-ToF)/Acquity i-Class spectrometer.

NMR measurements were performed using a Bruker Avance III HD 400 MHz spectrometer. The chemical shifts (δ) are reported in ppm and referenced against the solvent residue. UV-vis measurements in solution were recorded in the range 190–1100 nm using quartz cuvettes with a path length of 1 cm by means of an Agilent Cary 5000 UV-vis-NIR dual-beam spectrophotometer.

Diffuse reflectance measurements were carried out using an Agilent Cary 5000 UV-vis-NIR dual-beam spectrophotometer equipped with a diffuse reflectance accessory. Photoluminescence emission spectra in solution and in the solid-state were collected either with a Varian Cary Eclipse spectrofluorometer or a PerkinElmer LS55 fluorescence spectrometer.

DSC and TGA measurements

Thermogravimetric analysis (TGA) and differential scanning calorimetry analysis (DSC) were performed using a PerkinElmer series 7 thermal analyzer in the temperature range between 100 and 400 °C (20 °C min⁻¹) under nitrogen flow (40 mL min⁻¹).

X-ray diffraction

Single-crystal X-ray diffraction data of H_4L and **3** were collected with $\text{CuK}\alpha$ radiation using a Rigaku 007HF diffractometer equipped with VariMax confocal mirrors, an AFC11 goniometer, a HyPix-6000 detector, and an Oxford Cryosystems low-temperature device operating at 100 K. The diffractometric data for compounds **1c** and **2** were collected with $\text{MoK}\alpha$ radiation using a Rigaku FRE+ diffractometer equipped with VHF VariMax confocal mirrors, an AFC12 goniometer, a HyPix-6000 detector, and an Oxford Cryosystems low-temperature device operating at 100 K. Data collection and processing were performed using CrysAlisPro (Rigaku Oxford Diffraction).³² The structures were then solved with the ShelXT³³ structure solution program (using

the Intrinsic Phasing solution method) and by using Olex2³⁴ as the graphical interface with their models refined with version 2018/3 of ShelXL³⁵ using least squares minimization.

Powder X-ray diffraction analyses were performed using a Bruker D8 ADVANCE equipped with CuK α radiation and a LYNXEYE detector in 1D mode. The scan step was set to 0.05° and a scan speed of 0.5 s per step in the range from 4 to 30° (2 θ) was used. Experimental patterns were then compared with those calculated from single-crystal X-ray diffraction analysis by means of DIFFRAC.EVA.

TD-DFT calculations

Theoretical calculations were carried out at the density functional theory (DFT)²⁶ level by using the Gaussian 16³⁶ commercial suite of computational software on H₄L by adopting the PBE0²⁷ hybrid functional paralleled by different basis sets, namely, 6-31G, 6-311G, 6-311+G(d,p)³⁷ and Ahlrichs split-valence double- ζ plus polarization (pVDZ) sets, both in their original form³⁸ and in Weigend's²⁸ recent formulation (def2-SVP), and the corresponding triple- ζ plus polarization def2-TZVP.³⁹ Notwithstanding numerous attempts, including the variation of the SCF convergence algorithm and the energy optimization threshold, the optimization of excited state ES #1 was unsuccessful with the largest basis sets. The validation of the computational setup was carried out by comparing the results from TD-DFT calculations with the experimental values, in particular the absorption and the emission wavelengths (λ_{abs} and λ_{em} , respectively) for H₄L. Among the remaining basis sets, absorption and emission energies were calculated both in the gas phase and in DMSO solution, solvation being implicitly considered by means of the polarizable continuum SCRF model in its integral equation formalism (IEF-PCM), describing the cavity of the complexes within the reaction field (SCRF) through a set of overlapping spheres.²⁹ Very similar results were obtained (with τ angles varying within 1.5° and absorption energies within 0.07 eV), with an optimal balance between the reliability of the calculated parameters and the computational costs obtained with the def2-SVP basis set (Table S7 in the ESI†).

Finally, the results achieved with the PBE0 functional were compared with those obtained with the hybrid exchange–correlation functional using the Coulomb-attenuating method CAM-B3LYP,⁴⁰ including long-range corrections.⁴¹ Unfortunately, this functional largely overestimated both absorption and emission energies and was eventually discharged (CAM-B3LYP/def2SVP: gas phase, $\lambda_{\text{abs}} = 279.2$ nm, $\lambda_{\text{em}} = 393.0$ nm; DMSO $\lambda_{\text{abs}} = 284.1$ nm, $\lambda_{\text{em}} = 406.2$ nm). The effect of the mutual orientation of the carboxylic groups was investigated by optimizing H₄L separately not only in the structural conformation, showing the OH groups disposed one above the other, but also in the alternate disposition. The energy difference between the two isomers was found to be negligible differing from the former by 4.94×10^{-4} Hartree (corresponding to 0.31 kcal mol⁻¹). Calculations were

extended to complex 4 at the same PBE0//def2-SVP theoretical level. For all the compounds, tight SCF convergence criteria and fine numerical integration grids were used. Optimized geometries were verified by harmonic frequency calculations, including the determination of thermochemistry parameters (zero-point energy ZPE corrections and thermal corrections to enthalpy and Gibbs free energy) and the calculation of FT-Raman frequencies. A complete natural population analysis (NPA) was carried out with the natural bond orbital (NBO)⁴² partitioning scheme to investigate the charge distributions. Absorption vertical transition energies, wavelengths, and oscillator strengths were calculated at the time-dependent (TD) DFT level, by evaluating the ten lowest excited states. The calculation of absorption and emission energies was carried out as outlined previously.^{43,44} The frontier Kohn–Sham molecular orbitals involved in the electronic absorption at the lowest energies are depicted in Fig. S11† for H₄L and Fig. S13† for the model complex 4. The absorption maximum at the lowest energy was calculated at the TD-DFT level by considering the lowest vertical transition with non-negligible oscillator strength (GS \rightarrow ES #4). The natural transition orbitals (NTOs)³⁰ with the largest occupation for the transition GS \rightarrow ES #4 in the gas phase are depicted in Fig. S12 and S14† for H₄L and complex 4, respectively.

Emission energies were calculated for H₄L by evaluating the GS \rightarrow ES #1 energy at the geometry optimized for ES #1. Although any attempts to optimize ES #4 did not achieve an acceptable SCF convergence, the geometry of ES #1 in the gas phase converged to $\tau = 35.3^\circ$, thus suggesting the hypothesis that a direct crossing of ES #4 and ES #1 may occur at about $\tau = 30^\circ$. The energy curves in Fig. 7 were calculated by adapting a Morse-type equation to the electronic energy E as a function of τ :

$$E = E_e \cdot \{[1 - e^{a(\tau - \tau_e)}]^2\}$$

where, for each electronic state (GS or ES), E_e represents the energy of the relevant minimum, τ_e represents the equilibrium (optimized) torsion value, and a is defined as

$$a = \sqrt{\frac{k}{2|E_e|}}$$

with k being the force constant at the minimum energy value and being fitted with the calculated E_{abs} and E_{fluo} values (Tables 1 and S8;† $|a| = 1.826 \times 10^{-4}$ and 2.206×10^{-4} for the GS and ES #1, respectively). Solvation in absorption/emission processes was calculated within a non-equilibrium approach, by neglecting solvent molecular motion in the timescale of absorption and fluorescence processes.

Molden 6.2⁴⁵ and GaussView 6.0.16⁴⁶ were used to analyze Kohn–Sham (KS) molecular orbital (MO) compositions and energies. Chemissian 4.54⁴⁷ was used to evaluate the atomic orbital contributions to KS-MOs and to analyse the contribution of one-electron excitations to molecular

transitions. All calculations were carried out using the CINECA Galileo100 supercomputer.

Synthesis

Compounds **1a–1c** were prepared as previously described.⁷

Synthesis of 9,9'-methylene-bis(9-methylfluorene-2,7-dicarboxylic acid) (H₄L). In a 100 mL two-necked round-bottom flask, 40 mL of dry THF were cooled at $-78\text{ }^{\circ}\text{C}$ and then 2.4 mL of *n*-BuLi (2.5 M in hexane) were added under a N₂ atmosphere. After stirring for 15 min at the same temperature, a solution of **1c** (1.00 g; 1.45 mmol) in dry THF (20 mL) was added dropwise to the first solution and the resulting mixture was stirred for 1.5 h. CO₂ was then bubbled into the reaction mixture for 3 h, resulting in a colour change from pink to purple. The reaction mixture was then kept under a N₂ atmosphere overnight and the temperature was slowly raised to room temperature. An aqueous 1 M HCl solution (30 mL) was added to quench the reaction, resulting in the precipitation of the product which was collected by filtration, washed with water and ethyl acetate, and dried under vacuum (560 mg; 1.02 mmol; 70%). FT-IR (KBr 400–4000 cm⁻¹): 3437w, 2964br, 2594br, 1689vs, 1608s, 1585s, 1491w, 1469m, 1450ms, 1413s, 1302vs, 1259vs, 1115m, 1007w, 918m, 905m, 835m, 762s, 663m, 580w, 515m, 509m, 428m cm⁻¹. ¹H NMR (400 MHz, DMSO-*d*₆) δ 12.60 (br, 4H, OH), 7.61–7.47 (m, 8H), 7.30–7.19 (m, 4H), 3.31 (s, CH₂), 1.33 (s, 6H, CH₃) ppm (Fig. S13[†]). ¹³C{¹H} NMR (101 MHz, DMSO-*d*₆) δ 167.0, 150.5, 141.9, 129.4, 127.7, 124.7, 119.7, 49.3, 40.2, 28.6 ppm (Fig. S14[†]). ¹H-¹³C HMQC of H₄L in DMSO-*d*₆ Fig. S15[†] (TOF MS ES-) for (M-H)⁻ C₃₃H₂₃O₈⁻ (*m/z*): calcd 547.1393; found 547.1406 (Fig. S16[†]). Φ (DMF, quinine sulfate) = 0.209.

Synthesis of 2. An 8 mL glass vial was loaded with 6 mL of a DMA/H₂O mixture (2:1 v/v), a solution of H₄L in DMA (200 μ L, 0.25 M), and an aqueous solution of Cd(NO₃)₂·4H₂O (400 μ L, 0.25 M). The mixture was sonicated for a few minutes and then heated to 90 $^{\circ}\text{C}$ for 24 h. The mixture was then cooled to room temperature at a rate of 10 $^{\circ}\text{C h}^{-1}$. Colorless crystals were isolated and structurally characterized.

Synthesis of mixture 2 + 3. An 8 mL glass vial was loaded with 6 mL of a DMA/H₂O mixture (2:1 v/v), a solution of H₄L in DMA (200 μ L, 0.25 M), and an aqueous solution of Cd(NO₃)₂·4H₂O (400 μ L, 0.25 M). The mixture was sonicated for a few minutes and then heated to 120 $^{\circ}\text{C}$ for 24 h. The mixture was then cooled to room temperature at a rate of 10 $^{\circ}\text{C h}^{-1}$. Two different morphologies of colorless crystals were isolated and structurally characterized as compounds **2** and **3**.

Author contributions

Conceptualisation: MCA, RPD, EP, and MA. Data curation: MCA, EP, RPD, MA, SJC, JBO, and GE. Investigation: MCA, EP, RPD, MA, SJC, JBO, GE, and AP. Writing (original draft): MCA, RD, and EP. Writing (review and editing): all the

authors. Funding acquisition: CC and LP. Validation: all the authors.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

The authors kindly acknowledge CINECA for the computational resources on the Galileo100 supercomputer accessed within the ISCR project BIFluoex, Fondazione di Sardegna for financial support, CeSAR for PXRD facilities, and Daniele Mele for the TOC and the cover artwork. GP would like to thank the Italian Ministry of Education (MUR) for a postdoc scholarship (PRIN 2017 project 2017EKCS35).
