- In Section 2.4 the authors consider the computation of excess deaths, defined as the excess 8
- 9 of actual deaths over what might reasonably be expected given the situation in previous
- years. Equivalently we might characterise this as excess of actual deaths over what might 10
- 11 reasonably have been forecast given mortality experience up to the start of the pandemic.
- We argue that it is natural, therefore, to use mortality forecasting methodology for this 12
- 13 computation. This approach has the advantage both of allowing for predictable variation in
- exposures to risk at different ages over time, as the authors do, but also of incorporating 14
- predictable patterns of mortality change, which the authors do not. Mortality forecasting in 15
- the UK context generally assumes that mortality will improve, in line with experience over 16
- recent decades and this mortality improvement is embedded into forecasting methodology. 17
- 18 Different models for weekly Covid excess mortality have been proposed by, for example,
- Aburto et al (2021), the EuroMOMO group (e.g. Nielsen et al, 2021), Ellison et al (2021) 19
- 20 and OHID (2021), but all incorporate some combination of seasonal effects, holiday effects
- 21 and, critically, a log-linear mortality improvement trend based on historical data. One key
- difference is over what period that historical trend is estimated. Our approach (Ellison et at, 22
- 23 2021) is to assume that the long-term (60-year) trend applies, but the model also
- 24 incorporates a sporadic, unpredictable (age-independent) mortality improvement
- 25 component, in common with the classic mortality forecasting models of Lee and Carter
- 26 (1992) and Cairns, Blake and Dowd (Cairns et al, 2011). This latter component contributes © Royal Statistical Society 2025. All rights reserved. - 1 considerably to the uncertainty associated with any forecast and hence any estimate of
- 2 Covid excess mortality. Our estimates, an updated version of the original estimates in
- 3 Ellison et al (2021), are displayed in Figure 1. The estimated excess mortality is somewhat
- 4 larger than the authors' estimates, due to the allowance for mortality improvement in the
- 5 forecast model, but are similar to the ONS estimates. The ONS approach also ignores
- 6 mortality trends, and additionally fails to account for ageing population, as pointed out by
- 7 the authors. It seems that these two limitations, working in opposing directions, almost
- 8 exactly cancel each other out, the two approaches in Figure 1 yielding similar results
- 9 despite their somewhat differing assumptions.
- 10 The significant uncertainty resulting from the sporadic component in the forecasting model
- is noteworthy and suggests that precise inference about this aspect of the pandemic may be
- 12 elusive.
